#### Abstract

The report describes a compilation of the molecular spectroscopic parameters for a number of infrared-active molecules occurring naturally in the terrestrial atmosphere. The following molecules are included in this compilation: water vapor; carbon dioxide; ozone; nitrous oxide; carbon monoxide; methane; and oxygen. The spectral region covered extends from less than $1 \mu \mathrm{~m}$ to the far infrared, and data are presented on more than 100,000 spectral lines. The parameters included in the compilation for each line are: frequency, intensity, half-width, energy of the lower state of the transition, vibrational and rotational identifications of the upper and lower energy states, an isotopic identification, and a molecular identification.

A discussion is provided separately for each molecular species, indicating the sources and accuracy of the data and a general discussion of how the data were obtained.

# AFCRL Atmospheric Absorption Line Parameters Compilation 

## 1. INTRODUCTION

About 10 years ago a program was initiated to compile spectroscopic data on individual vibration-rotation lines of water vapor in the $2.7 \mu \mathrm{~m}$ region (Gates, et al, 1964).

This work continued resulting in a publication on the 2.05 and $2.7 \mu \mathrm{~m}$ bands of carbon dioxide (Calfee and Benedict, 1966) and a third publication on the 1.9 and $6.3 \mu \mathrm{~m}$ bands of water vapor (Benedict and Calfee, 1967). Other workers have published similar results on the $15 \mu \mathrm{~m}$ bands of $\mathrm{CO}_{2}$ (Drayson and Young, 1967), the $9.6 \mu \mathrm{~m}$ bands of $\mathrm{O}_{3}$ (Clough and Kneizys, 1965), the CO bands whose fundamental is near $5 \mu \mathrm{~m}$ (Kunde, 1967), the $\mathrm{CH}_{4}$ bands near 3 and $7.5 \mu \mathrm{~m}$ (Kyle, 1968) and the unpublished rotational water data calculated by Benedict and Kaplan in 1959 (see Goody, 1964, p. 184).

About 5 years ago an effort was initiated at AFCRL to continue this work with the aim of providing a complete set of data for all vibration-rotation lines of all naturally occurring molecules of significance in the terrestrial atmosphere. With such data at hand, it would be possible to compute the transmittance appropriate for atmospheric paths by first computing the monochromatic transmittance many times in a finely spaced frequency grid and then degrading the results to any appropriate spectral resolution. Up to now the following molecules have been included in this compilation: (1) water vapor; (2) carbon dioxide; (3) ozone; (4) nitrous oxide; (5) carbon monoxide; (6) methane; and (7) oxygen.
(Received for publication 26 January 1973)

All of these molecules except oxygen are minor constituents of the atmosphere, but nonetheless represent most of the absorption lines in the visible and infrared. Although there is some evidence for decreasing concentration with height of $\mathrm{N}_{2} \mathrm{O}$, CO , and $\mathrm{CH}_{4}$, it is probably reasonable for most purposes to assume that all of these gases except $\mathrm{H}_{2} \mathrm{O}$, and $\mathrm{O}_{3}$ are uniformly mixed by volume in the atmosphere unless other specific information is available. Table 1 provides concentrations and references for these "uniformly mixed gases". Water vapor and ozone are, of course, not uniformly mixed and an appropriate set of models useful in considering the radiation effects of these gases is proyided by McClatchey, et al, 1972.

Table 1. Concentrations of Uniformly Mixed Gases in Dry Air

| Constituent | ppm by volume | Reference |
| :---: | :---: | :--- |
| $\mathrm{CO}_{2}$ | 330 | Fink et al, 1964 |
| $\mathrm{N}_{2}{ }^{\circ}$ | 0.28 | Birkland and Shaw, 1959 |
| CO | 0.075 | Shaw, 1968 |
| $\mathrm{CH}_{4}$ | 1.6 | Goody, 1964 |
| $\mathrm{O}_{2}$ | $2.10 \times 10^{5}$ | Valley, 1965 |

## 2. DESCRIPTION OF COMPILATION

In order to compute the transmitance due to a given spectral line in the atmosphere it is necessary to describe the absorption coefficient as a function of frequency for each line. The four essential line parameters for each line are the resonant frequency, $\nu_{0}\left(\mathrm{~cm}^{-1}\right)$, the intensity per absorbing molecule, $\mathrm{S}\left(\mathrm{cm}^{-1} /\right.$ molecule $\mathrm{cm}^{-2}$ ) the Lorentz line width parameter, $\alpha_{0}\left(\mathrm{~cm}^{-1} / \mathrm{atm}\right)$, and the energy of the lower state, $\mathrm{E}^{4}\left(\mathrm{~cm}^{-1}\right)$. The frequency, $\psi_{0}$ is independent of both temperature and pressure (except for possibly very small pressure effects of less than 0.01 $\mathrm{cm}^{-1} / \mathrm{atm}$, which have been ignored here). The intensity, $S$, is pressure-independent, and, as discussed below, its temperature dependence can be calculated from $E$ " and $\nu$

The line half-width at half maximum, $\alpha$, is by definition proportional to the pressure, $p$, and its temperature dependence can be estimated as discussed below.

The precise line shape is a matter of some uncertainty, but in the derivation of line parameters from laboratory measurements; it is customary to start from the Lorentz shape (see Goody, 1964) given in Eq. (1).

$$
\begin{align*}
& k(\nu)=\frac{s \alpha / \pi}{\left(v-v_{0}\right)^{2}+\alpha^{2}}  \tag{1}\\
& s=f k(\nu) d v
\end{align*}
$$

The validity of Eq. (1) to describe the true line shape is subject to two limitations. The first, which can be precisely estimated and corrected for by the use of the Voigt shape, occurs when $\alpha_{0} P / \alpha_{D}<1.0$ where $\alpha_{D}$ is the doppler line width which varies with frequency, temperature and molecular mass as given in Eq. (2).

$$
\begin{equation*}
\alpha_{D}=\frac{\nu_{c}}{c}\left(\frac{2 \mathrm{kT}}{\mathrm{~m}}\right)^{1 / 2}=4.298 \times 10^{-7} \nu_{\Delta}(\mathrm{T} / \mathrm{M})^{1 / 2} \tag{2}
\end{equation*}
$$

where $M=$ molecular weight and here $k=$ Boltzmann's constant and $m=$ mass of a molecule.

For atmospheric molecules and infrared frequencies, modifications of the Lorentz shape begin to be required at pressures below 10 to 100 mb .

The second limitation concerns possible inadequacies of the Lorentz shape, especially in the distant wings of a line $\left(\left|\nu-\nu_{0}\right| \gg \alpha\right.$ ) (see Winters et al, 1964, and Burch et al, 1969) or when the long-range intermolecular forces responsible for collision broadening are dipole-quadrupole, leading to an exponent 1.75 rather than 2.0 for $\left(\nu-\nu_{0}\right)$, (Varanasi, 1972). Throughout this compilation we assume the validity of the Lorentz exponent.

The line intensity is temperature dependent through the Boltzmann factor and the partition function as indicated in Eq. (3) (the induced emission term has intentionally been omitted here),

$$
\begin{equation*}
S(T)=\frac{S\left(T_{s}\right) Q_{v}\left(T_{s}\right) Q_{r}\left(T_{s}\right)}{Q_{v}(T) Q_{r}(T)} \exp +\left[\frac{1.439 E^{\prime \prime}\left(T-T_{s}\right)}{T T_{s}}\right] \tag{3}
\end{equation*}
$$

where $E^{\prime \prime}$ (in $\mathrm{cm}^{-1}$ ) is the energy of the lower state of the transition and where $Q_{v}$ and $Q_{r}$ are the vibrational and rotational partition functions. The vibrational partition functions for the most abundant isotopes are given in Table 2. Partition functions for the other isotopes are similar. The temperature dependence of the rotational partition function is given by ( $\left.\mathrm{T} / \mathrm{T}_{\mathbf{s}}\right)^{\mathrm{j}}$ where j is also provided in Table 2 ( $\mathrm{T}_{\mathrm{s}}$ is taken to be $296^{\circ} \mathrm{K}$ ).

It is also necessary to know the temperature variation of $\alpha$. In the absence of specific indications discussed under each molecule, the equation $\alpha(T) / \alpha\left(T_{s}\right)=$ $\left(T / T_{s}\right)^{-n}$, with $n=1 / 2$, corresponding to the assumption of temperature-independent collision diameters, may be made. The validity of the assumption is more uncertain, the larger the dependence of the diameter on the particular rotation-vibration transition, (that is, it is most unrealistic for $\mathrm{H}_{2} \mathrm{O}$ and the low-J transitions of the other molecules). The theory of Tsao and Curnutte (1954) when applied to the determination of line width for $\mathrm{H}_{2} \mathrm{O}$ lines gives a wide variation of $n$ about the mean value of 0.62 (Benedict and Kaplan, 1959). Measurements made with a $\mathrm{CO}_{2}$ laser (Ely and McCubbin, 1970) indicate a value of $n=1.0$ for the P20 line of the $10.4 \mu \mathrm{~m} \mathrm{CO} 2$ band.

Table 2. Vibrational Partition Functions

| Molecule | j | Tempera- <br> ture | 175 | 200 | 225 | 250 | 275 | 296 | 325 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{H}_{2} \mathrm{O}$ | 1.5 |  | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.001 |
| $\mathrm{CO}_{2}$ | 1.0 |  | 1.0095 | 1.0192 | 1.0327 | 1.0502 | 1.0719 | 1.0931 | 1.1269 |
| $\mathrm{O}_{3}$ | 1.5 |  | 1.004 | 1.007 | 1.013 | 1.022 | 1.033 | 1.046 | 1.066 |
| $\mathrm{~N}_{2} \mathrm{O}$ | 1.0 |  | 1.017 | 1.030 | 1.048 | 1.072 | 1.100 | 1.127 | 1.170 |
| CO | 1.0 |  | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 |
| $\mathrm{CH}_{4}$ | 1.5 |  | 1.000 | 1.000 | 1.001 | 1.002 | 1.004 | 1.007 | 1.011 |
| $\mathrm{O}_{2}$ | 1.0 |  | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.000 | 1.001 |

An examination of Eqs. (1) and (3) indicates that it is necessary to know the $\nu_{0}, S\left(T_{S}\right), \alpha\left(P_{0}, T_{S}\right)$ and $E^{f \prime}$ value for each line in order to compute a spectrum. The data compilation described here contains these four quantities for each of the more than 100,000 lines between $1 \mu \mathrm{~m}$ and the far infrared belonging to the seven molecular species listed in Table 3. Additional identifying information is also supplied for each line as indicated below.

Table 3. Intensity Criteria for Lines Included in Compilation

| Molecule | Identification No. | Criterion Intensity* <br> Minimum at $\mathrm{T}=296 \mathrm{~K}$ | Existing Intensity <br> Minimum at $\mathrm{T}=296 \mathrm{~K}$ |
| :--- | :---: | :---: | :---: |
| $\mathrm{H}_{2} \mathrm{O}$ | 1 | $3 \times 10^{-27}$ | $3 \times 10^{-27}$ |
| $\mathrm{CO}_{2}$ | 2 | $2.2 \times 10^{-26}$ | $3.7 \times 10^{-27}$ |
| $\mathrm{O}_{3}$ | 3 | $3.5 \times 10^{-24}$ | $3.5 \times 10^{-24}$ |
| $\mathrm{~N}_{2} \mathrm{O}$ | 4 | $3.0 \times 10^{-23}$ | $4.0 \times 10^{-23}$ |
| CO | 5 | $8.3 \times 10^{-23}$ | $1.9 \times 10^{-23}$ |
| $\mathrm{CH}_{4}$ | 6 | $3.3 \times 10^{-24}$ | $3.3 \times 10^{-24}$ |
| $\mathrm{O}_{2}$ | 7 | $3.7 \times 10^{-30}$ | $3.7 \times 10^{-30}$ |

$*$ Units are $\mathrm{cm}^{-1} /\left(\right.$ molecule $\left.-\mathrm{cm}^{-2}\right)$

In order to establish the "Criterion Intensity Minimum" values given in Table 3, an extreme atmospheric path was considered, assuming the gas concentrations specified in Table 1 and maximum concentrations over the path of $3 \times 10^{24}$ molecules $/ \mathrm{cm}^{2}$ for water vapor and $1 \times 10^{20}$ molecules/cm for ozone. This extreme radiation path was the atmospheric path tangent to the earth's surface, and extending from space to space. Using this criterion, lines yielding less than 10 percent absorption at the line center would normally be omitted.

Although this absolute line intensity cutoff was established, it has not always been possible to achieve. In some cases it would have been unrealistic to push calculations to this limit when experimental confirmation fell far short. There are two specific areas in which this absolute cutoff has been violated: (1) In regions of very strong absorption, very weak lines above this absolute limit have been neglected; (2) Q-branch lines below this limit have occasionally been included where it is felt that the accumulation of many weak, closely spaced lines would still produce an appreciable absorption under some atmospheric circumstances. In some cases, (for example, $\mathrm{CO}_{2}$ ), sufficient laboratory measurements and theoretical work were available so that this limit was exceeded throughout the infrared.

In the past, line intensities have been defined in various units, different for each molecular species. It was common to define water vapor concentration in precipitable cm , or $\mathrm{g} / \mathrm{cm}^{2}$, in the path in question. On the other hand, the amount of $\mathrm{CO}_{2}$ and the other uniformly mixed gases in a path were often given in $\mathrm{cm}-\mathrm{atm}$ of gas at STP. In order to unify the units and ultimately to lead to less confusion, we decided to use the more fundamental quantity, molecules $/ \mathrm{cm}^{2}$ as a measure of absorbing gas abundance along the path. The appropriate conversion factors are:

$$
\begin{aligned}
& 1(\mathrm{~cm}-\mathrm{atm})_{S T P}=2.69 \times 10^{19} \text { molecules } / \mathrm{cm}^{2} \\
& 1 \mathrm{~g} / \mathrm{cm}^{2} \text { of } \mathrm{H}_{2} \mathrm{O}=3.34 \times 10^{22} \text { molecules } / \mathrm{cm}^{2}
\end{aligned}
$$

It was also decided, as indicated in Table 3, to define line (and band) intensities at $296^{\circ} \mathrm{K}$, the normal room temperature at which most measurements are made. Intensities of all bands are based on the total number of molecules of a given species of all isotopes in their normal abundance, not on the number of the particular isotope responsible for a given band. Isotopic abundance values for all molecules for which data are provided in the compilation are given in Table 4.

Half-widths of lines have been added where available. Details are discussed in the separate sections on individual molecules. In some cases, it is felt that insufficient data exist to warrant the inclusion of a variable half-width. In these cases, a mean, constant value has been inserted for each molecular species and values are given in Table 5.

A shorthand notation was adopted to identify the various isotopic species. It is easy to understand by considering the following examples for $\mathrm{CO}_{2}:{ }^{16} \mathrm{O}^{12} \mathrm{C}{ }^{16} \mathrm{O} \equiv$ $626,{ }^{16} \mathrm{O}^{13} \mathrm{C}^{16} \mathrm{O}=636$, and for $\mathrm{N}_{2} \mathrm{O},{ }^{14} \mathrm{~N}^{15} \mathrm{~N}^{16} \mathrm{O} \equiv 456$, etc. This same type of code is used for the other five molecules.

Table 4. Isotopic Abundances

| $\mathrm{H}_{2} \mathrm{O}$ | $\begin{aligned} & 161 \\ & 162 \\ & 181 \\ & 171 \end{aligned}$ | $\begin{aligned} & 0.90729 \\ & 0.000 .300 \\ & 0.00204 \\ & 0.000370 \end{aligned}$ | $\begin{aligned} & \mathrm{CH}_{4} \\ & \mathrm{CH}_{3} \mathrm{D} \end{aligned}$ | $\begin{aligned} & 211 \\ & 311 \\ & 212 \end{aligned}$ | $\begin{aligned} & 0.98815 \\ & 0.01110 \\ & 0.00060 \end{aligned}$ |

Table 5, Mean Half-width Values

| Molecule | Half-width ( $\mathrm{cm}^{-1} / \mathrm{atm}$ ) | References |
| :---: | :---: | :---: |
| $\mathrm{CO}_{2}$ | 0.07 | Yamamoto et al (1969) |
| $\mathrm{O}_{3}{ }^{2}$ | 0.11 | Lichtenstein et al (1971) |
| $\mathrm{N}_{2} \mathrm{O}$ | 0.08 | Toth (1971) |
| CO | 0.06 | Bouanich and Haeusler (1972) |
| $\mathrm{CH}_{4}$ | 0.055 | Varanasi (1971) (see Section 6.3) |
| $\mathrm{O}_{2}$ | 0.060 | Burch and Gryvnak (1969) |

A standard computer format was adopted for card or card-image input and is outhined below, the numbers between wertical lines representing the columns on an IBM card, and the letter-number combinations representing the computer format.* The first four quantities are: $\boldsymbol{\nu}=$ frequency in

| $\underline{\nu}$ | S | ¢ | $E^{\prime \prime}$ | Rotation and Vibration ID | Date | Isotope | Molecule |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1-10 | 11-20 | 21-25 | 26-35 | 36-70 | 71-73 | 74-77 | 78-80 |
| P10.3 | E10.3 | F5,8 | F10.3 | 5A6, A5 | 13 | 14 | 13 |

NIn the far Infrared $\left(\nu<100 \mathrm{~cm}^{-1}\right)$ a different format (F10.6) was occasionally chosen for the frequencies where high accuracy microwave measurements are available.
wavenumbers, $\mathrm{S}=$ line intensity in $\mathrm{cm}^{-1} /$ molecule $-\mathrm{cm}^{-2}$ at $296^{\circ} \mathrm{K}, \alpha=$ half-width in $\mathrm{cm}^{-1} \mathrm{~atm}$ at $296^{\circ} \mathrm{K}, \mathrm{E}^{\prime \prime}=$ energy of the lower state expressed in wavenumbers. The rotation and vibration identification are the most difficult to unify due to the differences in the quantum numbers required to define the upper and lower states for different kinds of molecules. The columns 36 through 70 are indicated below for water and ozone, both triatomic asymmetric molecules, where (') indicates upper state and (") indicates the lower state.

| $J^{\prime}, K_{a}^{\prime}, K_{c}^{\prime}$ | $J^{\prime \prime}, K_{a}{ }^{\prime \prime}, K_{c}^{\prime \prime}$ | $v^{\prime}{ }_{1} v_{2}^{\prime} v_{3}^{\prime}$ | $v_{1}{ }^{\prime \prime} v_{2}{ }^{\prime \prime} v_{3}{ }^{\prime \prime}$ |  |  |  |  |
| ---: | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 313 | $1 X$ | $3 I 3$ | $2 X$ | 312 | $1 X$ | $3 I 2$ | $1 X$ |

On the other hand, the quantum numbers specified for $\mathrm{CO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}$ between columns 36 and 70 are given below, where again (') indicates upper state and (') indicates lower state, and where r refers to Fermi resonance (see section on $\mathrm{CO}_{2}$ for more details). The identification system for methane differs from those described here and is described in the section on methane.

$$
\mathrm{v}_{1}^{\prime} v_{2}^{\prime} \ell^{\prime} v_{3}^{\prime} r^{\prime} \quad{ }_{5 I 2} \quad{ }_{5 x}^{\prime \prime}{ }_{1} v_{2}^{\prime \prime} \ell_{1}^{\prime \prime} v_{3}^{\prime \prime} r^{\prime \prime} \quad ~ P\left(J^{\prime \prime}+1\right)
$$

2x
The remaining fields specified above include the entry date of the datum (important primarily for our purposes), the isotopic code as described above, and the molecular identification as given in Table 3.

This work has now proceeded to the point where most of the data consistent with the above-mentioned line intensity limitation are fairly complete in the $1 \mu \mathrm{~m}$ to $100 \mu \mathrm{~m}$ region. The nature of the remaining uncertainties and omissions is discussed in the sections to follow. The data are frequency ordered on magnetic tape and are contained in records of 321 ten-character words per record. An initial control word indicates the number of words to follow ( 320 for a full record). Each such record contains 40 card images in the format described above. Thus, it is necessary after reading a record from the tape to decode it according to the format I10, 40 (F10.3, E10.3, F5.3, F10.3, 5A6, A5, 13, 14, 13). In order to aid those using other than Control Data Corporation equipment, Table 6 is provided. The column headed "External BCD Code" indicates the character representation actually used on the tape. If a computer having a different character code is being used, a simple cross-referencing program must be constructed. End of file markers are placed on the tape at the following frequency points: $500,1000,2000,5000,7500,10,000 \mathrm{~cm}^{-1}$ with a double end of file appearing at the end of the tape.

In Appendix A we have included a listing of a computer program for directly reading the tape on a CDC 6600 computer. (No card decks are available.) For other computer systems the user is left to his own devices. Appendix B provides a computer program and output for generating a synthetic spectrum for a constant pressure path.

Table 6. CDC 6000 Series Fortran Character Codes*

Interested parties can obtain a copy of the data tape described here by mailing a new, 7 -track, 800 BPI certified, 2400 ft long by $1 / 2 \mathrm{in}$. wide, magnetic tape to R. A. McClatchey, AFCRL (OPI), L. G. Hanscom Field, Bedford, Ma. 01730.

Due to the large amount of material included on this tape and the likelihood of errors, it is clear that the ultimate test of the accuracy and completeness of the data will be its use by many people in the scientific community. Therefore, we ask the cooperation of all who use these data to keep us informed of any apparent errors or omissions. We would appreciate the receipt of new laboratory data or theoretical work related to improving the data. We will then update this tape as sufficient new or revised data become available,

## 3. GENERAL REMARKS ON THE DERIVATION OF PARAMETERS

The four tabulated parameters, $\nu_{o}, E^{\prime \prime}, S$, and $\alpha$ must of course be derived from experimental observations, subjected to data reduction in the framework of the general theories of molecular spectroscopy. For the basic theory we refer the reader to such textbooks as Herzberg (1950) and Goody (1964). The complexity needed to approach the problem depends both on the type of molecule and the accuracy of the observational data. We here outline the equations and methods used for the general types of molecules, linear triatomic (and diatomic) $\mathrm{CO}_{2}, \mathrm{~N}_{2} \mathrm{O}$ and (CO); nonlinear triatomic, $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{O}_{3}$. Methane, $\mathrm{CH}_{4}$, a spherical top, is a special case, as is the diatomic $\mathrm{O}_{2}$, where unpaired electrons complicate the rotational structure of the ground and excited electronic states.

The energy states and the transition probabilities between energy states of the molecules are defined primarily by their numerical values as established by experiments and by the indices (quantum numbers) which identify them. In nearly all the cases of interest, mathematical relations of greater or lesser complexity relate the numerical properties to the quantum numbers. We here present the general relations used to generate the tabulated data. The specific data and exceptional cases are discussed later for each molecule.

### 3.1 Energy Levels and Line Positions

### 3.1.1 LINEAR MOLECULES

For the triatomic linear molecules $\mathrm{CO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}$, the vibrational states are characterized by three quantum numbers, which are zero or positive integers, of pure vibration, $v_{1}, v_{2}$, and $v_{3}$ and a fourth number $l_{2}=v_{2}, v_{2}-2 \ldots$ which represents the contribution of the bending mode to the angular rotation. In order to calculate the purely vibrational part of the energy ("the band origins"), it is necessary first to compute an unperturbed energy,

$$
\begin{align*}
& G_{v}^{u n p}, b_{y} G_{v}^{u n p}=\sum_{i} w_{i}^{n i}+\sum_{i j} \mathrm{X}_{i j} v_{i}{ }_{j}+\mathrm{g}_{22} 1^{2}+\sum_{i j k} v_{i} v_{j} v_{k}+ \\
& \sum_{i j k} v_{i} l^{2}+, \cdot \tag{4}
\end{align*}
$$

and then to incorporate the effects of resonance perturbation by combining all close lying levels with common $\langle$ and common symmetry in matrices whose diagonal elements are $G_{v}$ unp, whose off-diagonal elements are functions of additional molecular constants and the four quantum numbers, and whose eigenvalues are the vibrational energy $G$, For an excellent discussion and example, the reader is referred to the work on $\mathrm{N}_{2} \mathrm{O}$ by Pliva (1968).

This perturbation calculation results in the "mixing" of states whose $G_{v}$ unp are particularly close, so that the final description of the level by the original four quantum numbers is a poor one. Accordingly, it is useful to add a fifth index, the rank symbol $r$ to label in order of decreasing energy all such mixed states. We have adopted this procedure for $\mathrm{CO}_{2}$, where the mixed states are $\left(v_{1} v_{2} \ell_{2} v_{3}\right)$, $\left(v_{1}+1, v_{2}-2, l_{2}, v_{3}\right), \ldots$ etc. The highest value of $v_{1}$ and the lowest value of $v_{2}$ in each set are retained in the vibrational identification for all levels of the set.

In the present compilation, the above method was used to generate those energy levels which have not been observed, for all observed states the experimental value (averaged from various sources) was used.

The rotational energy of each vibrational state is given by:

$$
\begin{equation*}
E_{v}{ }_{v}=G_{v}+B_{v}\left[J(J+1)-l^{2}\right]-D_{v}\left[J(J+1)-l^{2}\right]^{2}+H_{v}\left[J(J+1)-l^{2}\right]^{3}+\ldots \tag{5}
\end{equation*}
$$

where the constants $B_{v}, D_{v}, H_{v}$ for each vibrational state are either determined by observation or calculated from a smaller number of rotational molecular constants. Whenever accurate constants have been observed, these are used, calculated values are reserved for the less important states. The equations for calculations of $B_{v}$ and $D_{v}$ are similar to those for $G_{v}$, and likewise require modification through the resonance perturbation. Evaluation from data of the small $H_{v}$ constants requires highly aectirate measurements extending to high $J$, so that in most cases these are fixed at zero, the non-zero values arise from resonances.

It will be noted in Eq. (4) that the vibrational energy depends on $\ell^{2}$. When $\ell \notin 0$ there are two levels for each $T \geq \boldsymbol{\ell}$, and this degeneracy is removed by rotation. The splitting ( $\ell$-type doubling") results in two sets of levels, designated $C$ and d. with elifferent effective rotational constants. When $\ell=1$ the splitting is inost important, and $\mathrm{B}_{\mathrm{c}} \neq \mathrm{B}_{\mathrm{d}}, \mathrm{D}_{\mathrm{c}} \neq \mathrm{D}_{\mathrm{d}}$, etc.; when $\ell=2, \mathrm{~B}_{\mathrm{c}}=\mathrm{B}_{\mathrm{d}}$ but $\mathrm{D}_{\mathrm{c}} \neq \mathrm{D}_{\mathrm{d}}$, etc.; whon $\ell=3$, the constants other than $H$ are the same. Resonances occasionally cause larger deviations.

When the linear molecule has a center of symmetry, as in $\mathrm{CO}_{2}$ with ${ }^{16} \mathrm{O}$ at both ends (but not when one oxygen is isotopically different), the paired atoms with zero nuclear spin cause zero statistical weight for rotational levels of a given parity. Thus, only even-J levels exist for the ground vibrational level and for all other levels with $\ell=0$ and $v_{3}$ even ( $" \Sigma_{g}^{+}$symmetry"); for levels with $\ell=0$ and $v_{3}$ odd ( $\Sigma_{u}^{-}$), only $J$ odd exists; when $\ell>0$, the $c-$ and $d$ - sublevels have different symmetry, so that for $\ell=1(\pi)$ the $J=$ odd levels are $c$ and the $J=$ even levels are $d$, etc. In the compilation symbols $c$ or $d$ are appended to the rotational quantum number of the lower state only when required, that is for $\ell \geq 1$ in the molecules without the center of symmetry. For example, R27C means 28c-27c; Q27C means 27d - 27 c .

The line frequencies are determined from the energy states by taking the differences corresponding to all allowed transitions. These depend on the familiar selection rules for the linear molecule:

$$
\begin{array}{r}
\text { When } \Delta l=0, \Delta \mathrm{~J}= \pm 1, \mathrm{c} \rightarrow \mathrm{c}, \mathrm{~d} \rightarrow \mathrm{~d} \\
\text { When } \Delta \ell=1, \Delta \mathrm{~J}= \pm 1, \mathrm{c} \rightarrow \mathrm{c}, \mathrm{~d} \rightarrow \mathrm{~d}, \\
\end{array} \quad \begin{array}{r}
\text { and } \Delta \mathrm{J}=0 \mathrm{c} \rightarrow \mathrm{~d} .
\end{array}
$$

The line positions may thus be conveniently represented for computational purposes as given series in $m$, where $m=J^{\prime \prime}+1$ for the $R-b r a n c h\left(J^{\prime \prime} \rightarrow J^{\prime \prime}+1\right)$, $m=-J^{\prime \prime}$ for the P-branch $\left(J^{\prime \prime} \rightarrow J^{\prime \prime}-1\right)$, and $m=J^{\prime \prime}$ for the $Q$-branch $\left(J^{\prime \prime} \rightarrow J J^{\prime \prime}\right)$. A different equation is needed for $Q$-branch of a given transition than for the $P$ and $R$ branches, because of the differences in the $\underset{\sim}{c}$ and $\underline{d}$ constants. The general equation is

$$
\begin{align*}
& \nu(m)=G_{v}+a m+b m^{2}+c m^{3}+d m^{4}+e m^{5}+f m^{6} \text {, with } a=\left(B_{v}^{\prime}+B_{v}^{\prime \prime}\right) ; \\
& b=\left(B_{v}^{\prime}-B_{v}^{\prime \prime}-D_{v}^{\prime}+D_{v}^{\prime \prime}\right) ; c=-2\left(D_{v}^{\prime}+D_{v}^{\prime \prime}\right) ; d=-\left(D_{v}^{\prime}-D_{v}^{\prime \prime}\right) ; \\
& e=3\left(H_{v}^{\prime}+H_{v}^{\prime \prime}\right) ; f=\left(H_{v}^{\prime}-H_{v}^{\prime \prime}\right) . \tag{6}
\end{align*}
$$

### 3.1.2 NONLINEAR MOLECULES

The nonlinear triatomic molecules $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{O}_{3}$ have similar basic structures. The formula for the vibrational energy is identical with Eq. (4), except that the quantum number $\ell$ and its associated constants do not exist. Vibrational resonances exist; in both $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{O}_{3}, \omega_{1} \sim \omega_{3}$, but these are of different symmetry, so that interaction between the band origins and identical rotational states occurs only in $(200,002)$, etc. In addition for $\mathrm{H}_{2} \mathrm{O}$, and much more closely for the 162 isotope, $2 \omega_{2} \approx \omega_{1}$, so that the properties of the higher vibrational levels must be computed by taking their resonances into account.

The rotational levels of these three-dimensional rotators, with three different reciprocal moments of inertia $A_{v}>B_{v}>C_{v}$ are labelled by three quantum numbers, $J, K_{a}, K_{c}$, with $K_{a}$ and $K_{c}$ assuming all values $0,1, \ldots J$, subject to $K_{a}+K_{c}=J$ or $J+1$. There are thus $2 J+1$ levels of a given $J$ (each again with a rotational statis tical weight of $2 J+1$ ); in addition there is a nuclear-spin statistical weight which gives alternate levels, depending on the odd or even parity of $K_{a}+K_{c}+v_{3}$, weights of 3 or 1 for $\mathrm{H}_{2} \mathrm{O}, 0$ or 1 for isotopically symmetrical $\mathrm{O}_{3}$. The normal progressions of energy within each $J$ is increasing with increasing $K_{a}-K_{c}$; occasionally inversions of a few paired levels may occur in excited vibrational states as a result of rotation-vibration interactions between close-lying states of like over-all symmetry in different vibrational levels. As $J$ increases, there is a tendency for the odd and even levels with $K_{a}$ or $K_{c}$ close in value to $J$ to approach very closely in energy, so that many apparently single lines are in reality degenerate pairs with unresolvable spacings. The range of $K_{a}, K_{c}$ in which these pairings occur, and the general spacing of the rotational levels is governed by the asymmetry parameter, $\kappa=$ ( $2 \mathrm{~B}-\mathrm{A}-\mathrm{C}$ )/(A-C), which for the ground vibrational states of $\mathrm{H}_{2} \mathrm{O}, \mathrm{HDO}, \mathrm{O}_{3}$ is respectively $-0.437,-0.689$, and -0.984 . As the parameter approaches -1 , the energy level formula approaches that of the symmetric top with $A>B=C$ namely,

$$
\begin{equation*}
E_{r}=\frac{B+C}{2} J(J+1)+\left(A-\frac{B+C}{2}\right) K_{a}^{2}-D_{J} J^{2}(J+1)^{2}-D_{J K} J(J+1) K^{2}-D_{K} K^{4} \tag{7}
\end{equation*}
$$

where the D's are centrifugal stretching constants, and where additional terms of powers higher in $\mathrm{J}^{2}, \mathrm{~K}^{2}$ are often required. For the asymmetric top molecules with $K \neq-1$, the rotational energy cannot be given by a closed formula, but requires the construction and diagonalization of matrices whose diagonal elements are given by Eq. (7) whose off-diagonal elements involve $\mathrm{B}-\mathrm{C}$ and two additional centrifugal stretching constants of power 4 , etc., and whose eigenvalues are the rotational energy. From the eigenvectors of the diagonalization, one obtains effective angular moments about each axis, $\left\langle P_{a}^{2}\right\rangle,\left\langle P_{b}^{2}\right\rangle,\left\langle P_{c}^{2}\right\rangle$, whose sum, $P^{2}=J(J+1)$ and one also obtains other coefficients necessary for the calculation of transition probabilities and other properties of each eigenstate.

The excited vibrational levels of water vapor may differ considerably from the ground state in their values of $A, B$, and $C$, and with a relatively high ratio of $A / \omega_{2}$ ( $\simeq 0.018$, as contrasted to 0.00059 for $\mathrm{B} / \omega_{2}$ in $\mathrm{CO}_{2}$ ), extensive overlapping occurs between rotational levels in nearby vibrational states, making the computation of the higher levels highly uncertain much beyond the limits of observation. Accordingly, for all except the lowest energy levels of the ground state it is preferable to use experimental rather than calculated values when available.

### 3.2 Line Intensities

The intensity of any line at frequency $\nu$ may be expressed in a purely formal way as:

$$
\begin{equation*}
S_{m}=\frac{\nu}{\nu_{0}}, S_{v}^{0} \cdot S_{R o t} \cdot F \tag{8}
\end{equation*}
$$

where $S^{\circ}{ }_{v}$ is the vibrational intensity of a nonrotating molecule at the vibrational origin, $\nu_{0} ; S_{\text {Rot }}$ is the rotational intensity for a rigid nonvibrating molecule and $F$ is a factor that takes into account the fact that both forms of motion are occurring simultaneously. In the rigid case, $F=1$, and if $S_{\text {Rot }}$ is normalized so that $\Sigma_{\text {Rot }} S_{\text {Rot }}=1$ and if the band extends over a limited frequency range so that $\nu / \nu_{0} \sim 1$, then $\mathrm{S}_{\mathrm{v}}^{\mathrm{o}}$ as defined by Eq. (8) is identical with the quantity usually denoted by $\mathrm{S}_{\mathrm{v}}$, the total band intensity, $\Sigma_{m} S_{m}$.
$S_{\text {Rot }}$ consists of a temperature-independent factor, the rotational line strength, $L_{R}$, common to all linear molecules, and a temperature-dependent Boltzmann factor,

If the sum of all transitions from $J^{\prime \prime}$ is normalized to the statistical weight $\mathrm{g}=2 \mathrm{~J}^{\prime \prime}+1$, and if one recalls the definition of the rotational partition function $Q_{\mathbf{r}}(T)=\Sigma g \exp \left(-1.439 \mathrm{E}_{\mathbf{R}} / T\right)$ (the summation is over all rotational levels of a given $v$ ), the normalization condition for all transitions ( $\Sigma S_{\text {Rot }}=1$ ) is fulfilled.

The equations for $L_{R}$ are as follows:

$$
\begin{array}{rll}
\Delta l & \Delta J & L_{R} \\
0 & 0 & \ell^{2}(2 \mathrm{~m}+1) / \mathrm{m}(\mathrm{~m}+1) \\
0 & \pm 1 & \left(|\mathrm{~m}|^{2}-\ell^{2}\right) /|\mathrm{m}| \\
\pm 1 & 0 & (|\mathrm{~m}|+1 \pm \ell)(\mathrm{m} \mp l)(2 \mathrm{~m}+1) / \mathrm{m}(\mathrm{~m}+1) \\
\pm 1 & \pm 1 & (|\mathrm{~m}| \pm 1 \pm \ell)(|\mathrm{m}| \pm \ell) /|\mathrm{m}| \tag{12}
\end{array}
$$

Equation (8) is exact with $F=1$ only for a rigid molecule. In the actual molecule, a number of factors may cause deviations, which however will vary regularly along the band. (A very few exceptional situations, "crossing perturbations", may also be recognized.) Depending on the precision of the measurements, the nonrigidity corrections ("F-factors") for the linear molecule, may be expressed as regular functions of the running index, $m$, as indicated in Eq. (13).

$$
\begin{equation*}
F=S_{\text {nonrigid }} / S_{\text {rigid }}=\left(1+a m+\mathrm{bm}^{2} \ldots\right) \tag{13}
\end{equation*}
$$

The first order theoretical correction is $F=(1+\zeta m)^{2}$ or $a=2 \zeta, b=\zeta$. For nearly all the intensities in the present compilation, a single $\zeta$ was used for each vibrational band; this is included in the tabulations of band parameters. More
refined measurements and theoretical calculations should; in future revisions of this compilation, permit the use of additional terms in Eq. (13).

For asymmetric top molecules, many more transitions are possible from each rotational level $\mathrm{JK}_{\mathbf{a}} \mathrm{K}_{\mathrm{c}}$, but the same general definitions hold. The values of $\mathrm{L}_{\text {Rot }}$ depend on the degree of asymmetry. Tabulations exist (Wacker, 1964) which are useful for orientation purposes. In the present work we either derive $L_{R}$ from the rotational constants, for pure-rotation bands and some fundamental bands, or make use of the tables.

The $F-$ factor corrections to the interisities become of considerable significance for most of the vibration-rotation transitions in $\mathrm{H}_{2} \mathrm{O}$. Various methods are used, based in part on theoretical considerations described later on, and in part on an arbitrary empirical adjustment of calculated values to the best observations.

A few general remarks should be made regarding the temperature dependence of $S_{V}{ }^{\circ} \cdot S_{V}{ }^{\circ}$ is proportional to the product of the relative population of the lower state, given by the vibrational Boltzmann terms $\exp \left(-1.439 \mathrm{G}_{\mathrm{v}}\right) / \mathrm{Q}_{\mathrm{v}}$ (with $\mathrm{Q}_{\mathrm{v}} \equiv$ ${ }_{v} \mathrm{~g}_{\mathrm{v}} \exp \left(-1.439 \mathrm{G}_{\mathrm{v}}\right)$ where $\mathrm{g}_{\mathrm{v}}$ is the degeneracy of the level, 1 when $\ell=0,2$ otherwise), and a temperature independent transition probability, $u_{v v}=\left|\int \tilde{\psi}_{v} u \psi_{v}{ }^{\prime} d \tau\right|^{2}, \psi$ being the dipole moment function, usually expressed as a Taylor's series expansion in the dimensionless normal coordinates. We rely on measurement to give the total absorption strength in a given spectral region. When the spectral resolution is sufficiently high to distinguish lines of the strongest band in the region, usually the one with the lower level $v=0$, from lines of all of the weaker "hot" or isotopic bands which aceompany it; no problems arise: The $S_{v}^{0}$ of each band, and accordingly the relative $\mu$ vvi is empirically established (along with favorable cases a determination of coefficients of the F -factor, leading to $\Sigma \mathrm{S}_{\mathrm{v}}$ for the region). However, most of the studies of quantitative band intensities have been made ander conditions where only the total intensity is observed and the strengths of the weaker lines, which contribute only a few percent of the total, estimated from theoretical relations.

When all the transitions in the region are of the same type (that is, have identical $\Delta v_{1}, \Delta v_{2}, \Delta v_{3}, \Delta()$, a good approximation to the relative transition probability is to use harmonic oscillator wave functions and to assume that the leading term in the expansion of $\mu$ is formed by the $\Delta v$ 's: for example if $\Delta v_{1}=2, \Delta v_{3}=1$, we require that this term be $\mu_{113} q_{1}^{2} q_{3}$ with $\mu_{113}=\partial^{3} \mu / \partial q_{1}^{2} \partial q_{3}$. Evaluation of the integral for arbitrary values of $v_{1}, v_{2}, v_{3} \rightarrow v_{1}+2, v_{2}, v_{3}+1$ then gives the ratio $\mu_{v^{\prime}}^{2} / \mu_{0201}^{2}=\left(v_{1}+2\right)!\left(v_{3}+1\right)!/ v_{1}!v_{3}!$. The general formula (for $\left.\Delta \ell=0\right)$ is $\left(v_{1}+\Delta v\right)!\left(v_{2}+\Delta v\right)!\left(v_{3}+\Delta v\right)!/ v_{1}!v_{2}!v_{3}!$. When $\Delta \ell= \pm 1$ similar relations involving integers hold. Use of more realistic wave functions corrected for an-
harmonicity with lower terms in the dipole expansion lead to very nearly the same ratios. Accordingly, for many transition regions this type of calculation is simple and acceptable.

When, however, as in the case of both $\mathrm{CO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}$, the resonance perturbations mix the vibrational wavefunctions, a region includes several bands with different basic transitions. For example, the $1.6 \mu$ region of $\mathrm{CO}_{2}$ contains four strong $\Delta \boldsymbol{\ell}=0$ bands, composing the resonance quartet $3001 \mathrm{r}-0$, with $\mathrm{r}=1,2,3,4$. If we assume that only the $\Delta v_{1}=3, \Delta v_{3}=1$ transition is involved, the relative transition probability of the four transitions should be given by the squared eigenvectors of the $\{301,221,141,061\}$ matrix, and the relative transition probability of the four hot transitions from 010 would be the same value (since $\Delta v_{2}=0$ ) multiplied by the squared eigenvectors of the $\{311,231,151,071\}$ matrix. These are not identical with the other eigenvectors, and all four hot bands have different transition probabilities. Moreover, the observed ground-state intensities are not proportional to the first set of eigenvectors. Inclusion of a second basic transition integral for $\Delta v_{1}=2, \Delta v_{2}=2, \Delta v_{3}=1$, together with the appropriate eigenvectors can, however, bring the observations in accord with calculation, if the ratio $\mu_{221}$ / $\mu_{301}$ is of the order of 0.1 . The ratio $231-0 / 221-010$ is 3 , and accordingly its inclusion increases the over-all -010/0 strength ratio and further shifts the relative probabilities. As one extends the calculations to lower states involving resonating groups with $\mathrm{v}_{2}=2,3$, and higher, required in the stronger bands of $\mathrm{CO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}$, the situation cannot be predicted in advance. However, calculations similar to those sketched above have been performed; then reliability depends on the accuracy of the input constants, but it is believed that such a computation is useful.

One must also note that in the isotopically modified molecules, the eigenvectors of resonating groups vary widely. Thus, the simple assumption of a constant isotopic abundance ratio for the intensities is very far from correct. It should be adequate however to assume that the relative intensities of the underlying transitions (301-0 and 221-0, in the example cited above) remain isotopically invariant.

It should also be remarked that the eigenvectors are rotationally dependent; the result would be a contribution to the $\mathrm{m}^{2}$ term in Eq. (9).

## 4. MOLECULAR SPECIES

### 4.1 Water Vapor

### 4.1.1 LINE POSITIONS

The frequencies of the lines of the principal isotope ( ${ }^{1} \mathrm{H}^{16} \mathrm{O}^{1} \mathrm{H}=\operatorname{Code} 161$ ) are calculated from a set of energy levels. These were obtained from the best available
data in all spectral regions by a smoothing process which is partly theoretical, partly empirical. The principal sources of data are identified and summarized in Table 7. The energy levels of the ground state, $v_{1} v_{2} v_{3}=000$, are by far the most extensive and accurate. They are based on a relatively small number ( 15 , at the present writing) of microwave lines whose frequencies are precise to $<0.00001 \mathrm{~cm}^{-1}$ ( 0.3 MHz ), and several much larger groups of pure rotational lines, whose frequency accuracy may range from 0,001 to $0.002 \mathrm{~cm}^{-1}$ for isolated lines measured with Michelson-type interferometers to 0.02 to $0.03 \mathrm{~cm}^{-1}$ for weaker or partially blended lines measured with conventional spectrometers. With the long absorption paths available through the atmosphere, the observed lines extend to quite high energy levels, and by somewhat less accurate measurements with fame sources, to still higher levels, so that pure rotation transitions connect all levels from 0 to more than $4000 \mathrm{~cm}^{-1}$. The 000 level is the lower state of the more than 50 vibration-rotation bands observed between 900 and $20,000 \mathrm{~cm}^{-1}$, so that these measurements provide combination differences (common upper level in two or more transitions) for the 000 state that confirm, and for some states greatly improve those of the pure-rotation lines. In particular, the recent laboratory measurements of the $1.9 \mu \mathrm{~m}$ region give low $-J$ energy differences that are selfconsistent to better than $0,001 \mathrm{~cm}^{-1}$. A theoretical smoothing of the totality of the observed microwave, pure-rotation, and combination-difference data, by leastsquares fitting to a 29 -constant Hamiltonian of the type described for $\mathrm{D}_{2} \mathrm{O}$ (Benedict et al, 1970) then yields the ground state energy levels used in the compilation, Inasmuch as none of the theoretical calculations have been successful in reproducing all of the available data to their apparent accuracy, the levels adopted for the current compilation are a calculated set for $E<2500 \mathrm{~cm}^{-1}$, and for higher energies are determined from observations. It is believed that the accuracy of lines involving these levels is $\pm 0.005 \mathrm{~cm}^{-1}$ for $\mathrm{E}^{\prime \prime}<1500 \mathrm{~cm}^{-1} ; \pm 0.02 \mathrm{~cm}^{-1}$ for $1500<\mathrm{E}^{\prime \prime}<3000 \mathrm{~cm}^{-1}$, and $\pm 0.05 \mathrm{~cm}^{-1}$ up to the tabulated limit, The levels of the other vibration-rotation states are then obtained by averaging the sums of the observed lines and the lower-state levels. When upper-state levels have not been observed, although transitions to them have expected intensities above the lower limit, estimated values are chosen, either by direct calculations using an appropriate approximate Hamiltonian, or by extrapolation of the observed series of upper-lower rotational energy differences.

For the isotopic forms 181 and 171, the ground-state energies were obtained in the same way, except with much less extensive data (respectively 12 and 9 microwave lines). The dependence on theoretical calculations for the smoothing is more extreme, and the data for levels higher than $1500 \mathrm{~cm}^{-1}$, the limit of observation, is quite uncertain. However, since the higher-order constants in the

Table 7. References for Water Vapor Energy Level Data (Contd)

The data sources are of five types: L, laboratory absorption measurements on water vapor or moist air at room temperature; LH, similar measurements in cells heated to $75-540^{\circ} \mathrm{C}$; F , laboratory measurements of emission from oxy-hydrogen ox oxy-acetylene flames, yielding $\sim 10^{19}$ molecules $/ \mathrm{cm}^{2} \mathrm{H}_{2} \mathrm{O}$ at $+2500-3500 \mathrm{~K} ;$ A, measurements of solar radiation through the atmosphere, containing $10^{22}-10^{25}$ molecules/cm ${ }^{2}$ U observations of the ratioed spectrum of sunspot/photosphere, also containing about $10^{19}$ mol $/ \mathrm{cm}^{2}$ at $\sim 3600 \mathrm{~K}$. Isotopic symbols are appended when enriched samples were studied, underlined when a majox component, dashed when moderately increased above natural abundance. The range of vibrational and rotational levels is a rough indication of the extent of levels obsexvable down to the intensity limit of $S^{\circ}\left(\mathrm{cn}^{-1} / \mathrm{mol} \mathrm{cm}^{-2}\right.$ ), corrected to 296 K , with the resolving power used. The ground state, $(v=0)$ is implied in all regions.

* In reference t, the observed contapination of the sample by deuterium to give the mpo abundances varying from $10-200$ times normal was not reported,
theoretical fit were constrained near their values in $\mathrm{H}_{2} \mathrm{O}-161$, the tabulated line positions for all pure-rotation lines should be accurate to $\pm 0.5 \mathrm{~cm}^{-1}$. Upperstate levels for these molecules are likewise available only for the strongest lines, so that the uncertainties of weak lines here might approach $\pm 1 \mathrm{~cm}^{-1}$.

The asymmetrically substituted HOD (162) molecule has been studied, both in the microwave and infrared regions with thoroughness comparable to 161 , so that the frequency data, for the $000,010,100,020,110$, and 030 bands should be of the same accuracy as for 161 . The 001 and 011 levels may have errors larger by a factor of five.

Quite reliable data can be calculated for the pure-rotation spectra of isotopic forms 182, 172, and 282, which are only of very minimal importance in the atmosphere. Weak lines in vibration-rotation bands of 182 (as yet unobserved, except for a few lines in 100-000) also have been included by estimating constant vibrational shifts from 162.

### 4.1.2 LINE INTENSITIES

The intensities of pure rotation lines were calculated by a program in which the effects of vibration-rotation interaction on both the rotational eigenfunctions and on the dipole moment were included. The eigenfunctions were obtained from a Hamiltonian with 25 independent constants which gave an excellent fit to the energy levels, and the dipole moment was expressed as a linear expansion in the dimensionless normal coordinates:

$$
\begin{equation*}
\mu=\mu_{\mathrm{e}}+\left(\partial \mu / \partial \mathrm{q}_{1}\right) \mathrm{q}_{1}+\left(\partial u / \partial \mathrm{q}_{2}\right) \mathrm{q}_{2}+\left(\partial \mu / \partial \mathrm{q}_{3}\right) \mathrm{q}_{3}+\ldots \tag{14}
\end{equation*}
$$

The $\partial \mu / \partial \mathrm{q}_{\mathrm{i}}$ coefficients in this expression were obtained from the $\mathrm{S}_{\mathrm{v}}^{0}$ values of the three fundamental bands by the equation $S_{v_{i}}^{O}=4.16 \times 10^{-19} \nu\left(\partial \mu / \partial q_{i}\right)$. The algebraic signs of $\partial \mu / \partial \mathrm{q}_{\mathrm{i}}$ were chosen so that the observed vibration-rotation effects on intensities were reproduced in the fundamental bands of $\mathrm{H}_{2} \mathrm{O}$ and verified by noting that these and only these choices also gave a reasonable fit to the band intensities and interaction effects in the isotopic molecules. The value of the permanent moment in the equilibrium configuration, $\mu_{e}=1.847 \mathrm{D}$ (Clough and Beers, 1973), was derived from Stark Effect measurements on 8 microwave lines in three isotopic water molecules ( $161,162,262$ ), and is in excellent agreement with recent molecular-beam measurements (Dyke and Muenter, 1972). The uncertainty in the calculated intensities should result from inaccuracy of the $\partial \mu / \partial q_{i}$ coefficients and neglect of higher terms in the expansion; accordingly, it should be of minor importance for low J lines, and is estimated to be less than 1 percent for $E^{\prime \prime}<1000 \mathrm{~cm}^{-1}$ and less than 10 percent for all lines in the tabulation, with the possible exception of the very low probability lines in such branches as $R_{53}, Q_{55}$, etc. (Benedict, Classen and Shaw, 1952).

The intensities of vibration-rotation lines are more difficult to calculate, because they differ from those of the rigid asymmetric rotor by three interrelated effects: (1) the centrifugal effects, as used above for pure rotation; (2) the fact that the asymmetry, and hence the rotational eigenfunctions, are vibrationally dependent; and (3) the fact that for all vibrations above 010 , the rotational levels of like symmetry and equal J in different vibrational levels are at energies sufficiently close that the vibrational eigenfunctions are rotationally dependent, and in special cases "perturbations" lead to abnormal mixing and intensities. Oniy the first-named effect has been incorporated in the computations, through the method described by Benedict and Calfee (1967). Table 8 lists the constants used for each band. The footnotes to Table 8 list the sub-branches which are observed to disagree in a regular way from the results of the calculation, and which were adjusted accordingly. The lines that are exceptionally perturbed (effect 3) are identified by the symbol $P$ following $K_{c}^{\prime} ;$ for these the total intensity of the two "interacting" lines was divided as required by the calculated vibrational mixing ratios or further adjusted to agree with measurements. No general statement can be made concerning the accuracy of the intensities of individual lines; for the low-J lines of the strongest bands it should be within $\pm 10$ percent, within a factor of two for other lines of sufficient intensity $\left(>10^{-25} \mathrm{~cm}^{-1} / \mathrm{mol-cm}{ }^{-2}\right)$ to appear in laboratory and/ or solar spectra, and within an order of magnitude for the weakest lines.

The intensities of the isotopic lines of species 181 and 171 were taken equal to those of 161 multiplied by the abundance factor lexcept for the cases of strong perturbation where the vibrational mixing ratios are different). The asymmetric isotopic species 162 is widely different, so that a completely independent calculation of its intensities, in both pure rotation and vibration-rotation hás been made. The band parameters are included in Table 8.

### 4.1.3 LINE WIDTHS

Recent high-resolution spectra of air-broadened or $\mathrm{N}_{2}$-broadened water vapor lines (Brault, 1972, private communication) have in general confirmed the calculations of Benedict and Kaplan (1959) to $\pm 10$ percent. A striking discrepancy is, however, observed (Blum et al, 1972) for the lines of highest $J$ which are much narrower than the lower limit of $0.032 \mathrm{~cm}^{-1} \mathrm{~atm}^{-1}$ which was imposed on the calculated value by choosing a minimum collision diameter equal to the kinetictheory diameter. If the Anderson Theory (Anderson, 1949) is modified by eliminat ing a distance of closest approach (that is, setting the kinetic theory collision diameter equal to zero) the calculated half-width at half -height of $16_{1,16^{-15}}{ }^{-15,15}$ is lowered from 0.032 to $0.0098 \mathrm{~cm}^{-1}$, still slightly above the observed value ( 0.0086 ). The validity of the theory is thus in question for high-J transitions but a revised

Table 8. Water Vapor Band Intensity Data and Interaction Coefficients

Nobes Horable 8 .
(1) Insufficient data to establinh interaction coefficients; these are assumed dentical vith corresponding band of 161.
(2) fower line for ftrong lines (haghel) upper line for others.
(x) Many lines, especialiy those whe antwarced resonance with 001 , require spectall treatment.

(A) Very close teshnance of these two dtates at $k$ a aly trancition
calculation with $b_{\text {min }}=0$ does reproduce the empirical results better than the original calculation. Accordingly this has been incorporated in the current tabulation. As in previous computations, no vibrational dependence of the width has been included. The widths of the isotopic lines ( 181 and 171) have been set equal to those of 161 ; for 162 a new calculation, with $\mu_{e}=1.847, q_{a i r}=2.62 \times 10^{-26}$ esu and $b_{\min }=0$ has been made, where $\mu_{e}$ is the dipole moment of water, $q_{a i r}$ is the effective quadrupole moment of the colliding gas and $b_{\min }$ is the collision diameter.

### 4.2 Carbon Dioxide

### 4.2.1 LINE POSITIONS

The line positions and lower-state energies of each of the significant isotopic modifications of $\mathrm{CO}_{2}$ were calculated for each band by a rotational formula for the linear molecule including terms up to $D_{v} J^{2}(J+1)^{2}$. For some of the higher states involving Fermi resonances of high rank, an additional term $H_{v} \mathfrak{J}^{3}(J+1)^{3}$ was required. A very few of the vibrational levels are involved in a rotational perturbation, for which special calculations were needed as discussed below. The constants for each level are summarized in Table 9. For each isotopic species the band constants form a self-consistent set; that is, if a vibrational state appears more than once, as either initial or final state, its value of $G_{v}, B_{v}, D_{v}$ (and occasionally $H_{v}$ ) is the same. This requirement results in some deviations of the smoothed final line positions from their best observed'values, but in general the positions of observed lines, up to $J=40$, will be within $\pm 0.01 \mathrm{~cm}^{-1}$ of the tabulation.

The constants were calculated for each isotopic species separately, using a set of constants similar to those of Chedin and Cihla (1972), for 626, 636, and 628, but the isotopic sets were not consistently readjusted to fit a potential function. However, for isotopic forms for which the data are less extensive, approximate isotopic relations were used.

The data used for the band constants are taken from various sources. The highest precision data are those for the laser transitions 00011-10001 and 0001110002 in the 626 isotope. The measurements of Gordon and McCubbin (1965, 1966), Oberly et al; (1968), and Drayson (1967) provide the data for interrelations among the lowest states. The most extensive data for the higher states are those from the planet Venus, as observed and summarized by Connes et al, (1969).

The vibrational notation may not be familiar to all users, and accordingly will be explained at this point. Five digits are used for each state, in order, $v_{1} v_{2} \ell v_{3} r$. The fifth digit, $r$, takes the possible values $1,2, \ldots v_{1}+1$, and serves to locate the level in the Fermi resonating group of $v+1$ levels; $v_{1}, v_{2} \ell, v_{3} ; v_{1}-1\left(v_{2}+2\right) \ell$, $v_{3} ; \ldots 0,\left(v_{2}+2 v_{1}\right)^{\ell}, v_{3}$. The value of $r$ decreases with increasing energy. (In

this scheme, $v_{2}$ is always equal to $\left.\boldsymbol{\ell}.\right)$ The desirability of labelling the states in Fermi resonance by the same symbols except for $\mathbf{r}$ is to emphasize the very important role played by the Fermi resonance, which is very nearly exact for most of the groups. It must also be emphasized very strongly that the long-established custom of calling the upper level of the $\left(10^{0} 0,02^{0} 0\right)$ resonance at $1388.18 \mathrm{~cm}^{-1}$, $\boldsymbol{\nu}_{1}$, and the lower level at $1285.41,2 \boldsymbol{\nu}_{2}$, is not only confusing the issue, but is wrong, since the now ten year old work of Amat and Pindert (19651 has shown that the unperturbed position of $2 \nu_{2}^{\circ}$ lies above that of $\nu^{\circ}{ }_{1}$, in the 626 isotope. This is also true in 627,628 , and 828 , but in $636,637,638$, it lies below. It seems vastly preferable always to label the upper level 10001 and the lower 10002.

### 4.2.2 LINE INTENSITIES

The intensity data (summarized in Table 10) are based on quantitative studies of resolved lines where such exist; and where not, on total intensities in a given region. The relations between the strengths of the principal band in a region and its associated weaker "hot" and isotopic neighbors were based on computations relating the transition moments to the vibrational eigenfunctions, taking into account terms up to the quartic in the molecular constants, with particular attention to the degree'of Fermi mixing in the states, and an approximate calculation of the "unperturbed" (before Fermi mixing) transition moments. This procedure appears to give fairly good agreement for the ground-state and "first-hot" transitions in such Fermi groups as 2001-0000 and 3001-0000, and seems adequate for estimating strengths of higher unobserved hot bands. However, when experimental data are available (Burch, 19701, as for the 12201-11102 band at $828.28 \mathrm{~cm}^{-1}$, these were used.

For the isotopic molecules, empirical data were again used where available, as for 628 bands which are forbidden in the symmetric molecules. When the isotopic bands overlap stronger bands of 626, the abundance ratios were used to estimate the total strength of a group, but the particular Fermi parameters were used to divide the strengths.

The influences of vibration-rotation interactions on line intensities has been measured in some cases. As a generalization, it can be said that these are usually negligible for the parallel bands ( $\left.\boldsymbol{\ell}^{\prime}-\boldsymbol{l}^{\prime \prime}=0\right)$ but become of considerable importance for all the perpendicular bands $\left(\boldsymbol{\ell}^{\prime}-\boldsymbol{\ell}^{\prime \prime}=\underline{t} \underline{1}\right)$ except those in the $15 \mu \mathrm{~m}$ region. For all the other bands, Coriolis-type resonances are responsible for inducing a large part of the transition moment in the R- and P-branches, thus "borrowing" intensity from the stronger parallel bands, while leaving the $\mathbf{Q}$ branches unchanged. Accordingly, the latter may remain very weak (or in some cases be unobservable - for example, the 410 group). We have used the approximate equation $\mathbf{S}_{\mathbf{m}}=\mathbf{S}^{0}{ }_{\mathbf{v}}\left(1 \mathrm{tm} \boldsymbol{\zeta}_{\mathrm{v}}\right)^{2}$ to correct for this interaction, with the values

of $\boldsymbol{\zeta}^{\mathbf{v}}$ included in Table 9. Note that when $\zeta_{\mathrm{v}}$ is larger than 0.01 , the total band strength, if defined as the sum of the Q , R- and P-branch lines, $\boldsymbol{\Sigma}_{\mathrm{m}} \mathrm{S}_{\mathrm{m}}$, may be much larger than $S^{0}{ }_{v}$, its value when $\zeta_{v}=0$. The entry in Table 10 is $S_{v}{ }_{v}$, not $\sum_{\mathrm{m}}^{\Sigma} \mathrm{S}_{\mathrm{m}}$.

As a higher-order effect of Coriolis interactions, transitions with $\boldsymbol{\ell}^{\prime}-\boldsymbol{\ell}^{\prime \prime}=$ +2 also become allowed, the effect increasing as $\mathrm{m}^{2}$, so that a few such bands are intense enough to appear; here we list the value of $\mathbf{S}_{\mathbf{v}}^{0}$ in the formula $S_{m}=S_{v}^{o}\left(|m|+m^{2}\right) \exp \left[\left(-1.439 E^{\prime \prime}\right) / T\right] / Q_{r}$.

There are also a few special cases of near-or crossing-perturbations, where a normally véry weak band "borrows" intensity from a stronger neighbor. A notable example is represented by the bands at $4808.186 \mathrm{~cm}^{-1}$, where the $40002-01101$ band with zero intensity, resonates with the $21113-01101$ band at $4807.692 \mathrm{~cm}^{-1}$. The positions and intensities of the individual lines are here calculated using an appropriate Coriolis constant and dividing the strength of 21113-01101 according to the degree of perturbational mixing.

### 4.2.3 $\mathrm{CO}_{2}$ LINE HALF-WIDTHS

The half-widths for $\mathrm{CO}_{2}$ were assigned by a linear function of the rotational quantum number. The work of Yamamoto, Tanaka and Aoki (1969) gave methods of estimating half-widths for the $15 \mu \mathrm{~m}$ and $4.3 \mu \mathrm{~m}$ regions, but the differences between their limited comparisons of calculated values and laboratory measurements did not seem to warrant any more complicated procedure in arriving at a half-width dependence upon J for $\mathrm{CO}_{2}$.

### 4.3 Orone

The band centers and intensities of all bands included in the compilation are given in Table 11.

The pure rotational transitions of ozone have been calculated using the molecular constants of Lichtenstein, Gallagher, and Clough (1971) obtained from microwave measurements. Transitions with upper state $J$ less than 61 and intensities greater than $3.5 \times 10^{-24} \mathrm{~cm}^{-1} / \mathrm{mol}-\mathrm{cm}^{2}$ have been tabulated using a value of $\boldsymbol{\mu}=0.53 \mathrm{D}$ for the dipole moment. Lines with $\mathrm{K}_{\mathrm{a}}$ less than 10 should be accurate to $0.001 \mathrm{~cm}^{-1}$. Multiplets up to $\mathrm{K}_{\mathrm{a}}=12\left(\approx 100 \mathrm{~cm}^{-1}\right)$ have been observed and the calculated contours agree within the experimental accuracy (see Gebbie et al, 1966). At higher values of $K_{a}$, the calculations become increasingly less certain. However, even the highest value of $K_{a}$ included in the listing (that is, $K_{a}=20$ ) is substantially less \#an the value of K for which the calculation is divergent. The mean line width has been determined to be 0.11 (Lichtenstein et al, 1971).

| 3041.200 | $1.10 \times 10^{-19}$ | 003 | 000 | 666 |

For the $\boldsymbol{\nu}_{\mathbf{2}}$ fundamental of ozone, upper-state molecular constants have been obtained from microwave data by Tanaka and Morino (1970a). For a discussion of the determination of the band center see Tanaka and Morino (1970b). Transitions up to $J=60$ with intensities greater than $3.5 \times 10^{-23} \mathrm{~cm}^{-1} / \mathrm{mol}-\mathrm{cm}^{2}$ have been tabulated. The dipole moment constant for the $\nu_{2}$ fundamental has been taken as $\left(\partial \mu / \partial \mathrm{q}_{2}\right) \mathrm{q}_{2}=0.048 \mathrm{D}$ giving a band intensity of $6.7610^{-19} \mathrm{~cm}^{-1} / \mathrm{mol}-\mathrm{cm}^{2}$ based on the measurements of McCaa and Shaw (1968).

The $\boldsymbol{\nu}_{\mathbf{3}}$ and $\boldsymbol{\nu}_{\mathbf{1}}$ regions of the ozone spectrum have been studied by Clough and Kneizys (1965, 19661, and Tanaka and Morino (1968). The positions of the $\boldsymbol{\nu}_{1}$ and $\nu_{3}$ transitions for the main isotope are expected to be accurate to $0.01 \mathrm{~cm}^{-1}$ for $J$ less than 40 and $K_{a}$ less than eight with a degradation of accuracy for higher values of the quantum numbers. In conformity with the results of McCaa and Shaw (1968), the band intensity of $\boldsymbol{\nu}_{3}$ has been taken as $130 \times 10^{-19} \mathrm{~cm}^{-1} / \mathrm{mol}-\mathrm{cm}^{2}$.

Also, more lines have been included than were given in the report of Clough and Kneizys (1965). Goldman, et al (1970) have found that the absorption by large ozone amounts could not be satisfactorily explained without introducing the hot bands and the isotopic bands. Since the energy levels are known for the 101, the 100 and the 010 vibrational levels, transitions for the $101 \leftarrow 100$ and $101 \leftarrow 001$ bands may be calculated directly. The line positions for these bands with $J$ less than 30 and $\mathrm{K}_{\mathrm{a}}$ less than six are presumed accurate to $+0.03 \mathrm{~cm}^{-1}$. The line positions for the $011-010$ hot band have been obtained by applying a calculated shift of $-21.0 \mathrm{~cm}^{-1}$ to the $\boldsymbol{\nu}_{\mathbf{3}}$ transitions of the main isotope. For $J$ less than 30 and $\mathrm{K}_{\mathrm{a}}$ less than six an error of up to $1 \mathrm{~cm}^{-1}$ may be expected. For the $\mathbf{0 0 2} \leftarrow 001$
hot band, a calculated shift of $-15.0 \mathrm{~cm}^{-1}$ has been applied to the $\boldsymbol{\nu}_{\mathbf{3}}$ transitions of the main isotope. In this case, the rotational levels of the upper- and lowervibrational states are not accurately described, and these lines must be considered to be useful only for their general contribution to the low-resolution absorption in the region. These shifts have been calculated using harmonic frequencies and anharmonic corrections determined from an analysis of the available vibrational data.

For the 668 and 686 isotopes, shifts of $-13.1 \mathrm{~cm}^{-1}$ and $-34.1 \mathrm{~cm}^{-1}$ respectively have been determined from force constant calculations using the structural constants given by Tanaka and Morino (1968). These shifts have similarly been applied to the original $\nu_{3}$ line calculations, neglecting the isotopic effect on the rotational constants. Consequently, only the general contribution to low -resolution spectra by these lines is valid. The intensities of the hot bands and the isotopic bands have been determined by applying the appropriate Boltzmann correction, isotopic abundance factor, dipole moment matrix element value, and degeneracy factor to the intensities of the $\boldsymbol{\nu}_{3}$ fundamental.

Although the addition of the isotopic bands and the hot bands gives improved agreement between calculated absorption and the observed absorption for large ozone amounts, it appears that an intensity anomaly still exists. In the P branch region ( $\sim 1000 \mathrm{~cm}^{-}$) the calculated intensity is evidently too low, while in the R branch region the calculated intensity is too high. Until better intensity measure ments are available, it will be difficult to obtain experimental $F$ factors (see Section 3.2).

The $\left(\nu_{1}+\nu_{3}\right)$ combination band $(101-000)$ has been observed and analyzed using the rigid rotor approximation by Trajmar and McCaa (1964). The value of the band center was found to be $2110.79 \mathrm{~cm}^{-1}$. The resolution and calibration accuracy of the observed spectra were not good, so that the line positions up to $J=20$ and $\mathbf{K}_{\mathbf{a}}=4$ are accurate to only $0.3 \mathrm{~cm}^{-1}$. The error in line position is expected to be significantly greater for higher quantum numbers. The band intensity for the tabulated lines is $1.19 \times 10^{-18} \frac{\mathrm{~cm}^{-1}}{\mathrm{~mol} / \mathrm{cm}^{2}}$.

The $\left(\boldsymbol{\nu}_{1} \mathrm{t} \boldsymbol{\nu}_{2} \mathrm{t} \boldsymbol{\nu}_{3}\right)$ combination band $(111-000)$ at 2785.241 has been studied by Snider and Shaw (1971). The rigid rotor analysis used gives line positions for $J$ less than 25 and $K_{a}$ less than 6 accurate to $0.1 \mathrm{~cm}^{-1}$. The intensity for this band is $2.46 \times 10^{-20} \frac{\mathrm{~cm}^{-1}}{\mathrm{~mol} / \mathrm{cm}^{2}}$ and was also obtained from McCaa and Shaw (1968).

Constants for the $3 \boldsymbol{\nu}_{\mathbf{3}}$ band (003-000) have been obtained from a second order calculation using the results of Tanaka and Morino (1968). The band intensity has been taken as $1.12 \times 10^{-19} \mathrm{~cm}^{-1} /$ molecule $-\mathrm{cm}^{-2}$ from McCaa and Shaw (1968). The accuracy of the line positions should not be in error by more than $\pm 5 \mathrm{~cm}^{-1}$.

### 4.4 Nitrous Oxide

Nitrous oxide is an asymmetric linear molecule ( $\mathrm{N}-\mathrm{N}-\mathrm{O}$ ) with three fundamental vibration-rotation bands, $\boldsymbol{\nu}_{1}, \boldsymbol{\nu}_{2}$, and $\boldsymbol{\nu}_{3}$, at 1284.907, 588.767, and 2223.756 $\mathrm{cm}^{-1}$, respectively, for the main isotope. As for $\mathrm{CO}_{2}, \boldsymbol{\nu}_{1} \cong 2 \boldsymbol{\nu}_{2}$ so that Fermi resonance occurs between these two levels, causing shifts of the band centers from the positions otherwise expected. Five different isotopes provide significant absorption. When no reference to a particular isotope is made, the most abundant one, 446 , is implied. The abbreviated notations and natural abundances of each isotope used to calculate intensities of the isotopic bands are (446), 99.043 percent; (456), 0.358 percent; (546), 0.358 percent; (448), 0.199 percent; and (447), 0.040 percent. These values differ slightly from those given in Table 4, the difference arising from slight differences in the oxygen and nitrogen natural abundances taken from the 48th edition and the 42 nd edition of the Handbook of Physics and Chemistry.* The 48th edition values were used in the construction of Table 4. These abundance differences are very small, but can be accounted for by modifying the line intensities accordingly.

### 4.4.1 LINE POSITIONS

Table 12 lists the constants used to calculate the line positions. Values of the vibrational energy, G , are relative to the $00^{\circ} 0$ level for each isotope and are probably accurate to a few thousandths of a $\mathrm{cm}^{-1}$ for the 446 isotope. The uncertainty is much greater for some of the levels of the rarer isotopes. The majority of the constants for the 446 isotope and a few for the other isotopes are from Pliva (1964, 1968a, 1968b). Most of the other values have been derived by Benedict (private communicationsl from a variety of data.

Line positions for the P- and R-branches can be calculated by inserting the constants from Table 12 into Eq. (6). The selection rules are: AJ $=0, \pm 1 ; \Delta \boldsymbol{l}=0$, $\pm 1$; and $J=0 \div \neq \mathrm{J}=0$. The allowed values of J for a given vibrational level must be taken into account in order to determine missing lines. For example, in a $\boldsymbol{\phi} \leftarrow \boldsymbol{\Delta}$ band ( $\boldsymbol{\ell}^{\prime}=3-\boldsymbol{\ell}^{\prime \prime}=2$ ) the following lines are missing because of rotational energy levels that are not allowed: P1, P2, P3, QO, Q1, Q2, RO and R1.

A few lines of the $10^{\circ} 1,06^{\circ} 0,06^{2} 0$, and $10^{\circ}{ }_{1}-10^{\circ} 0$ bands are shifted from the positions based on the constants in Table 12 because of Fermi interactions. These are discussed in more detail below and summarized in Table 15.

### 4.4.2 LINE INTENSITIES

Each band system contains a main band and associated hot bands that arise from transitions from excited energy levels with the same changes $\Delta v_{\mathbf{1}}, \boldsymbol{\Delta} \mathrm{v}_{\mathbf{2}}$, and $\Delta v_{3}$ in the vibrational quantum numbers as in the main band. The change $\Delta \boldsymbol{l}$ may be either 0 or $\pm 1$ within the same band system. For example, the $0^{\circ} 01$ band is the main band in a system that also contains the hot bands $01^{1} 1-01^{1} 0,02^{\circ} 1-02^{\circ} 0$, $02^{2}{ }_{1}-02^{2} 0,10^{\circ} 1-10^{\circ} 0$, and many others from higher excited energy levels. The relative intensities of the hot bands decrease with increasing value of the lower energy level because of the decrease in its population. Thus, only a few of the hot bands are usually significant. Corresponding bands of the rare isotopic molecules are also part of the system. The main band of the common isotope accounts for 78 percent to 89 percent of the entire system for $296^{\circ} \mathrm{K}$ samples, depending on the band system.

Table 13 summarizes the normal band systems containing lines with intensities greater than $4 \times 10^{-23}$ molecules ${ }^{-1} \mathrm{~cm}^{2} \mathrm{~cm}^{-1}$. Each band system is identified by the main band whose center position is given. The intensities are based on recent measurements of the quantity $\int(-1 / u) \ell n T d \boldsymbol{L}$ by Burch et al, (1971a,1971b,1971c, 1972). The integration was performed over the entire band system, and $u$ is the $\mathrm{N}_{2} \mathrm{O}$ thickness in molecules $\mathrm{cm}^{-2}$. The intensity, $\mathrm{S}_{\mathrm{Q}}$, of only the Q -branch of the band at $1974.571 \mathrm{~cm}^{-1}$ is listed because the P and R branches contain no lines with intensities above the cut-off. The Q-branch may be significant although each of its lines is very weak because they occur very close together. Bands containing the $06^{\circ} 0$ and $06^{2} 0$ levels are not listed because the band systems are very weak. However, as a result of Fermi interaction between a few of the rotational levels, the intensities of the corresponding lines are anomalously high and their positions arc shifted. These lines are discussed in more detail below.

Table 14 lists the intensities of each of the bands with lines above the cutoff intensity, nominally $4 \times 10^{-23}$ molecules ${ }^{-1} \mathrm{~cm}^{2} \mathrm{~cm}^{-1}$. Each line entry in the table corresponds to a given band, and blank lines occur before and after each band system. Note that 16 bands are listed for the $00^{\circ} 1$ band system, whereas only 1 or 2 bands are listed for some of the weaker systems.

Each rotationallevel within a vibrationallevelfor which quantum number $\boldsymbol{\ell} \neq 0$ is split into two sublevels normally indicated by " $c$ " and " $d$ " (see section 3.1.1). A band involving two A levels, or two $\pi$ levels, or one of each level consists of two sub -bands, one from the $c$ portion of the lower level and one from the $d$ portion. The $c-c$ portion of the first sub-band contains only P- and R-branches, whereas the d . - c portion contains the Q -branch. Similarly, the $\mathrm{d}-\mathrm{d}$ and the $\mathrm{c}-\mathrm{d}$ portions of the second sub-band contain the P t R branches and the Q -branch, respectively. The intensities, $\mathbf{S}_{\mathbf{v}}$, given in Table 14 are the total for both sub-bands.

The intensities of the majority of the bands have been calculated from the experimental values for the entire band systems listed in Table 13. Calculating the intensity of an individual band from that of the entire band system involves the population of each energy level, the degeneracy of each level, and the relative transition probabilities.

In some of the band systems, the experimental results indicate that the transition probabilities are the same for all bands within a given system. However, as in the $12^{\circ}{ }^{\circ}$ band system, for example, , the transition probabilities are greater for the $\mathbf{1 3}^{\mathbf{1}} 0-01^{1} 0$ and $14^{\circ} 0-02^{\circ} 0$ bands than for the $\mathbf{1 2}^{\circ} \mathbf{0}$ band. These differences in transition probabilities were found experimentally by comparing the relative intensities of several isolated lines within the system.

Equations relating the intensities of individual lines to that of the entire band are given in Section 3. These are applicable to the $\mathbf{N}_{2} \mathbf{O}$ bands listed in Table 14 with the exception of two forbidden $\mathrm{A} \leftarrow \boldsymbol{\Sigma}$ bands, $\mathbf{0 2} \mathbf{2}^{\mathbf{2}}$ and $\mathbf{1 2} \mathbf{2}^{\mathbf{2}} \mathbf{0}$, and those listed in Table 15. The factor ((see Section 3 Eq. (13)) that accounts for the Coriolis vibration-rotation interaction can be assumed to be zero for all bands in Table 14, except for the $\mathbf{0 3}^{\mathbf{1}} \mathbf{0}$ and $\mathbf{1 1}^{\mathbf{1}} \mathbf{0}$ bands; $\boldsymbol{\zeta}$ equals approximately -0.01 and -0.007, respectively, for these bands.

Young (1972) has tabulated the relative intensities of the lines within a given band for which the Coriolis interaction is negligible. A large fraction of the intensity of a band system is in the main band; therefore, uncertainties in the relative transition probabilities within a band system do not seriously increase the uncertainty of the main-band intensity calculated on the basis of that of the entire band system. Thus, the percent of uncertainty in the intensity of the main band is approximately the same as that for the entire band system, whereas the uncertainty for the hot bands may be greater.

### 4.4.3 FORBIDDEN BANDS AND PERTURBED LINES

As a result of Coriolis interactions, transitions with $\boldsymbol{\ell}^{\prime}-\boldsymbol{\ell}^{\prime \prime}= \pm 2$ become allowed. Two $\mathbf{N}_{2} \mathrm{O}$ bands of interest that arise from such "forbidden" transitions are the $02^{2} 0-00^{\circ} 0$ and $12^{2} 0-00^{\circ} \mathbf{0}$ bands centered at 1177.750 and $2474.785 \mathrm{~cm}^{-1}$, respectively. The relationship between the intensities of the individual lines within a band is different for these bands than'for normal bands. As in the case of $\mathrm{CO}_{2}$, the intensities are given by Eq. (15) where $\mathrm{S}_{\mathrm{v}}{ }^{0}$ a $1.36 \times 10^{-5}$ molecules ${ }^{-1} \mathrm{~cm}^{2} \mathrm{~cm}^{2^{\circ}}{ }^{-1}$ for the $02^{2 \mathrm{c}_{0}}$ band and $\mathrm{S}_{\mathrm{v}}{ }^{0}=9.5 \times 10^{-6}$ molecules- $\mathrm{cm}^{2} \mathrm{~cm}^{-1}$ for the $12^{2 \mathrm{c}_{0}}$ band.

A few rotational levels of the $06^{\circ} 0$ vibrational state (centered at $J=46$ ) and the $06^{2} 0$ state (centered at $J=28$ ) are perturbed by the corresponding levels of the $10^{\circ}$ 1 state to such an extent that the normally very weak lines "borrow" enough

Table 15. Parameters of Perturbed Lines of N20

1) The perturbed line positions of the $10^{\circ} 1$ band are from observed values by Tidwell et al, (1960).
2) The calculated positions of perturbed lines of the $06^{\circ} 0$ and $06^{2} 0$ bands were determined from known perturbed positions of the $10^{\circ} 1$ lines and Toth's (1971a) values of the line separations.
3) The calculated positions of the perturbed $10^{\circ} 1-10^{\circ} 0$ lines were determined from Toth's (1971a) results and the positions of the unperturbed lines calculated on the basis of the constants in Table 12.
4) The perturbed line intensities of the $06^{\circ} 0$ and $06^{2} 0$ bands are based on the intensities of the unperturbed lines of the $10^{\circ} \mathbf{1}$ band and Toth's (1971a) results. The unperturbed line intensities of the $10^{\circ} 1$ and $10^{\circ} 1-10^{\circ} 0$ bands are based on the band intensities given. in Table 13 and Young's (1972) relative line intensities.
intensity from the $10^{\circ}{ }_{1}$ lines to appear, at the same time shifting the positions of the lines related to these rotational levels (Toth, 1971a). The resulting positions and intensities of the affected lines have been calculated separately and are given in Table 15. The R27 and R29 lines of the $10^{\circ} \mathbf{1}-\mathbf{1 0}^{\circ} \mathbf{0}$ band are not listed in the table because the changes in their intensities and positions are negligible.

### 4.4.4 LINE HALF-WIDTHS

Several workers have measured the half-widths of $\mathbf{N}_{2} \mathbf{O}$ lines broadened by $\mathbf{N}_{\mathbf{2}}$, which is a good approximation to broadening by air. Toth (1971b) has recently measured the widths of lines in the R branches of the $10^{\circ} \mathbf{1}$ and $\mathbf{0 2}{ }^{\circ} \mathbf{1}$ bands directly from observed spectra with a small correction for the effect of the spectrometer slitwidth. Margolis (1972) has used the same method to measure the lines in both the P - and R-branches of the $\mathbf{0 0}^{\mathbf{0}} \mathbf{2}$ band. The results of these two workers are in
good agreement, indicating that there is little, if any, dependence on vibrational mode. Lowder's (1972) recent measurements on the $00^{\circ} 1$ band show approximately the same dependence on $J$ as do the results of Toth and Margolis. although Lowder's values averaged approximately 10 percent less. Oppenheim and Goldman (1971) have measured half -widths indirectly by applying band models to low -resolution spectra of a wide variety of $\mathbf{N}_{2} \mathbf{O}$ samples. Their results are in fair agreement with those of Margolis and Toth. Fraley et al, (1962) reported an average value of $0.05 \mathrm{~cm}^{\mathbf{- 1}}$ a t ${ }^{\mathbf{- 1}}$ for lines in the $00^{\mathbf{o}} \mathbf{1}$ band; this value is considerably lower than those reported by the workers mentioned above.

We have adopted half-widths of $\mathbf{N}_{\mathbf{2}}$-broadened lines reported by Toth (1971b) to be used for atmospheric $\mathrm{N}_{2} \mathrm{O}$ lines near $296^{\circ} \mathrm{K}$. A few values are listed in the tabulation below; values for other J's can be found by interpolation and for other temperatures by assuming the 'half-widths are inversely proportional to the square root of temperature.

| J | $\mathrm{cm}^{-1} \mathbf{a t m}^{\mathbf{0}} \mathbf{o t}^{\mathbf{1}}$ |
| :---: | :---: |
| 1 | 0.0915 |
| $\mathbf{4}$ | 0.0948 |
| 10 | 0.0892 |
| 20 | 0.0812 |
| 30 | 0.0767 |
| 40 | 0.0748 |
| 50 | 0.0698 |
| 60 | 0.0604 |

### 4.5 Carbon Monoxide

For the CO bands, we have depended heavily on the work of Young (1968). Table 16 provides the rotational constants which were used to compute the line positions of the main isotope. The positions of the less abundant isotopes were computed from the appropriate constants for the 26 isotope by applying the ratio of reduced masses. The accuracy of the line positions in the main isotope is expected to be about $+0.001 \mathrm{~cm}^{-1}$. Theaccuracy of the line positions of the other isotopes will be somewhat less, about $\pm 0.01 \mathrm{~cm}^{-1}$.

The intensities for the fundamental and first two overtone bands were taken from Young and are reproduced in Table 17. The intensities for the isotopic bands were taken to be the same as for the 26 isotope reduced by the relative abundances given in Table 4 and the square of the frequency. The intensity of the fundamental appears to be known very accurately, perhaps within $t 2$ percent; the first overtone is less accurately known to $\pm 10$ percent; and the second overtone is known to $\pm 4$ percent (see Young and Eachus, 1966); Burch and Gryvnak (1967). Half-width values have been added to the compilation following the work of Hunt et'al, (1968).

Table 16. Rotational Constants Used in the Calculation of CO Line Positions

| Symbol | Value |
| :--- | :---: |

### 4.6 Methane

This molecule is a spherical top, in the rigid rotor approximation. It has tetrahedral ( $\mathrm{T}_{\mathrm{d}}$ ) symmetry in the rest configuration of its nuclei. Rotationvibration interactions are complicated even for its simplest infrared-active bands. Starting from the molecular Hamiltonian and the electric dipole-moment operator, transition energies, selection rules, and intensities may be calculated. However, the techniques and the results are complex, and it is not convenient to summarize them here. Therefore, the user is referred to the original papers on this subject John (1968), Schaffer et al, (1939), Hecht (1960), Moret-Bailly (1961), Herranz (1961), Fox (1962), Dang-Nhu (1969), and Susskind (1972).

For the purpose of the present data compilation, we have established the following conventions in notation. The isotopic species ${ }^{12} \mathrm{CH}_{4},{ }^{13} \mathrm{CH}_{4}$, and ${ }^{12} \mathrm{CH}_{3} \mathrm{D}$ are denoted by the digits 211,311 , and 212, respectively, in columns 75 through 77. The quantum numbers for the initial and final states of a transition are specified in columns 36 through 69 as follows:

$$
\begin{array}{ccccccccc}
v^{\prime}{ }_{1} v^{\prime}{ }_{2} \ell_{2}^{\prime} v^{\prime}{ }_{3} \ell_{3}^{\prime} v^{\prime}{ }_{4} \ell_{4}^{\prime} \ell^{\prime} & v_{1}^{\prime \prime} v_{2}^{\prime \prime} \ell_{2}^{\prime \prime} v_{3}^{\prime \prime} \ell_{3}^{\prime \prime} v_{4}^{\prime \prime} \ell_{4}^{\prime \prime} \ell^{\prime \prime} & J^{\prime} R^{\prime} & C^{\prime} & N^{\prime} & J^{\prime \prime} R^{\prime \prime} & C^{\prime \prime} & N^{\prime \prime} \\
1 \mathrm{X} & 811 & 1 \mathrm{X} & 811 & \text { 1X } 2121 \mathrm{~A} 11111111 \mathrm{X} 2121 \mathrm{~A} 1111111
\end{array}
$$

except for type E symmetry which has for C the format 1X 1A1 instead of 1 A 1111. The initial and final state vibrational and rotational quantum numbers have their usual meanings. To avoid ambiguity, we establish some further conventions for the present data compilation. The selection rule $\mathrm{C}^{\prime}-\mathbf{C}^{\prime \prime}$ on $\mathbf{T}_{\mathbf{d}}$ symmetry is always taken to be $A_{1}-A_{2}, A_{2}-A_{1}, E-E, F_{1}-F_{2}$, or $F_{2}-F_{1}$. The numbering scheme for the N's
begins with $1,2,3 \ldots$ Whenever possible, N increases with increasing groundstate energy; the stronger lines correspond to the selection rule, $\mathbf{N}^{\prime}-\mathbf{N}^{\prime \prime}=0$.

This section describes methane spectral data in the 3 to $8.5 \mu \mathrm{~m}$ region. The following bands, as summarized in Table 18, have been included: $\boldsymbol{\nu}_{2}, \nu_{3}, \boldsymbol{\nu}_{4}, \boldsymbol{\nu}_{2^{+}}$ $\nu_{4}, 2 \nu_{4}$.

Table 18. Methane Bands Included in Data Compilation

| Isotope | Band | Center $\left(\mathrm{cm}^{-1}\right)$ | Upper <br> State | Lower State | $\begin{gathered} \text { Intensity } \\ \left(\mathrm{cm}^{-1} / \mathrm{mole}^{-\mathrm{cm}^{-2}}\right) \end{gathered}$ |

h. $1 / 89$ times value for corresponding band of 211 isotope
i. Armstrong and Walsh (1960)
j. $1 / 100$ times value for $\boldsymbol{\nu} 3$ of 211 isotope
k. $1 / 15$ times value for $v_{3}$ of 211 isotope

It is planned to add other weak but significant bands in this spectral region at a later time.

Many line positions, together with their absolute intensities and widths, have been included in the present data compilation, even though the corresponding quantum number assignments are uncertain or unknown at this time. It must be stressed that much of the needed theoretical and experimental research on spectra of methane is still incomplete. Consequently, a large portion of the data compilation should be considered tentative and subject to revision at a later time.

### 4.6.1 LINE POSITIONS

The band $\boldsymbol{\nu}_{3}$ at $3.3 \mu \mathrm{~m}$ is the strongest infrared-active vibration-rotation fundamental of $\mathrm{CH}_{4}$. High-resolution measurements of line positions for ${ }^{12} \mathrm{CH}_{4}$ in the range 2884 to $3141 \mathrm{~cm}^{-1}$ have been used. See Henryet al, (1970), and Barnes et al, (1972). Guantum number assignments for the allowed lines from 2840 to 3167 $c^{-1}$ were made by Bobin and Fox (1973) on the basis of fourth-order perturbation theory. Some forbidden lines were assigned by Barnes et al, (1972) using third order theory. Spectroscopic parameters determined for the ground-state and for $\boldsymbol{\nu}_{\mathbf{3}}$ of $\mathbf{C H}_{4}$ are listed in Tables 19 and 20, respectively. The corresponding band of the isotopic species ${ }^{13} \mathrm{CH}_{4}$ has been measured from 2873 to $3123 \mathrm{~cm}^{-1}$. The assignments of McDowell (1966) with some modifications were used. The corresponding spectroscopic parameters are listed in Table 23.

Table 19. Spectroscopic Parameters for Ground State of ${ }^{12} \mathrm{CH}_{4}$

| Parameter | Value $\left(\mathrm{cm}^{-1}\right)$ |
| :---: | :---: |
| $B$ | $5.24059 \pm 0.00006^{\mathrm{a}}$ |
| $\mathrm{D}_{\mathrm{s}}$ | $(1.086 \pm 0.003) \times 10^{-4}$ |
| $\mathrm{D}_{\mathrm{t}}$ | $(4.403 \pm 0.099) \times 10^{-6} \mathrm{~b}$ |

a. Barnes et al, (1972)
b. Ozier et al, (1970). The error bar is derived from the values given by Barnes et al, (1972) and Husson and Dang Nhu (1971).

The band at $7.7 \mu \mathrm{~m}$ is the next strongest fundamental of ${ }^{12} \mathrm{CH}_{4}$. High resolution measurements in the 1225 to $1393 \mathrm{~cm}^{-1}$ range made by Botineau (1972) were used to obtain spectral line positions. Quantum-number assignments for the allowed lines, to $\mathrm{J}=12$ for the R and Q branches, and $\mathrm{J}=13$ for the P branch, were made by Michelot and Fox, (1973) on the basis of a fourth order calculation. For $\mathrm{J}=13$ to 15 in the Q branch only, and for some $\mathrm{J}=13 \mathrm{R}$-branch lines, quantumnumber assignments were taken from the work of Husson and Poussigue (1971). No forbidden lines of this band have been included in the data compilation yet. The determined spectroscopic parameters are given in Table 21. For $\boldsymbol{\nu}_{4}$ of ${ }^{13} \mathrm{CH}_{4}$, the measurements of Kyle et al, (1970), extend from 1226 to $1359 \mathrm{~cm}^{-1}$, and possibly further. The assignments of Kyle et al, (1970) with some modifications were used; spectroscopic parameters appear in Table 24.

*Michelot and Fox (1973)

The $\boldsymbol{\nu}_{\mathbf{2}}$ fundamental at $6.5 \mu \mathrm{~m}$ is relatively weakly infrared-active, by virtue its Coriolis interaction with $\boldsymbol{\nu}_{\mathbf{4}}$. Quantum-number assignments are based on the results of Dang Nhu (1969) who developed a fourth-order theory and applied it to unpublished spectra of moderately high resolution. Spectroscopic parameters are listed in Table 22.

High-resolution spectra of $\boldsymbol{\nu}_{\mathbf{2}}+\boldsymbol{\nu}_{4}$ and $2 \boldsymbol{\nu}_{4}$ are available in the region of approximately 2450 to $3200 \mathrm{~cm}^{-1}$ (Plyler et al, 1960; and Hall, 1973). Quantum number assignments for $2 \boldsymbol{\nu}_{4}$ have been made on the basis of a third-order theoretical analysis. A partial analysis of $\boldsymbol{\nu}_{2}+\nu_{4}$ has been done in analogy with the quantumnumber assignments in the work of (Bregier, 1970; and Hilico, 1970), on $\boldsymbol{\nu}_{2}+\boldsymbol{\nu}_{3}$. Spectroscopic parameters for $\boldsymbol{\nu}_{2}+\boldsymbol{\nu}_{\mathbf{4}}$ and $\mathbf{2} \boldsymbol{\nu}_{\mathbf{4}}$ are given in Tables 25 and 26 respectively.

### 4.6.2 LINE INTENSITIES

Although it is recognized that it would be desirable to include in the data compilation all methane lines whose absolute intensity exceeds the cutoff specified in Table 3, it has not been possible to achieve this goal because of present experimental and theoretical limitations.

Absolute intensities for the allowed lines in $\boldsymbol{\nu}_{3}$ of ${ }^{12} \mathrm{CH}_{4}$ were calculated, starting from the measured values for $R(0) ; R(1)$, and $R(2)$. The relative intensities of forbidden lines (Barnes et al, 1972) were used for calculating their absolute intensities. The absolute line intensities for $\boldsymbol{\nu}_{3}$ of ${ }^{13} \mathrm{CH}_{4}$ were calculated on the basis of those for $\boldsymbol{\nu}_{3}$ of ${ }^{12} \mathrm{CH}_{4}$, together with the terrestrial ${ }^{12} \mathrm{C} /{ }^{13} \mathrm{C}$ ratio (see Table 4). Calculated and/or measured absolute band intensities are listed in Table 18.

Absolute line intensities for $\boldsymbol{\nu}_{4}$ have been calculated on the basis of the measured values for $R(0), R(1)$, and $R(2)$. For ${ }^{13} \mathrm{CH}_{4}$, absolute intensities were calculated as for $\nu_{3}$. Absolute band intensities are given in Table 18.

Absolute line intensities for $\boldsymbol{\nu}_{2}$, have been calculated on the basis of theoretical relative-line intensities and the experimental absolute band intensity in Table 18.

Absolute -line intensities for $\boldsymbol{\nu}_{2}+\boldsymbol{\nu}_{4}$ were determined from the solar spectra of Hall (1972), with an assumed $\mathrm{CH}_{4}$ air mass of approximately $4 \times 10^{19}$ molecules $/ \mathrm{cm}^{2}$ and an assumed temperature of $273^{\circ} \mathrm{K}$ and a pressure of 0.65 atm .

Absolute line intensities for $2 \boldsymbol{\nu}_{4}$ were calculated from the relative intensity formula of Fox (1962) together with the absolute band intensity in Table 18. The latter intensity was taken to be approximately $1 / 100$ of that for $\boldsymbol{\nu}_{3}$ of ${ }^{12} \mathrm{CH}_{4}$.

### 4.6.3 LINE WIDTHS

The J - and T-dependence of methane line widths is taken from the results of Varanasi et al, (1971, 1972) and Tejwani and Varanasi (1971). The only measured values of air -broadened $\mathrm{CH}_{4}$ half-widths are for multiples of $\boldsymbol{\nu}_{3}$ and $2 \boldsymbol{\nu}_{3}$ at $\mathrm{T}=$ $295^{\circ} \mathrm{K}$. For $\mathrm{J} \approx 1$ to $5, \boldsymbol{\gamma}^{\circ} \approx 0.061 \mathrm{~cm}^{-1} \mathrm{~atm}^{-1}$; for $\mathrm{J} \approx 15$ to $17, \boldsymbol{\gamma}^{\circ} \approx 0.048 \mathrm{~cm}^{-1}$ $\mathrm{atm}^{-1}$. These results agree with values calculated from $\mathrm{Y}^{\circ}$ for $\mathrm{CH}_{4}{ }^{-0}{ }_{2}$, assuming $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ with their partial pressures in air. Measurements and calculations of Yo for $\mathrm{CH}_{4}-\mathrm{H}_{2}$ in $\boldsymbol{\nu}_{4}$ suggest, but do not prove directly, that $\mathrm{Y}^{\circ}$ may be independent of vibration-rotation band. For the purpose of the present data compilation, we adopt the value $\boldsymbol{\gamma}^{0}=0.055 \mathrm{~cm}^{-1} \mathrm{~atm}^{-1}$ for all $\mathrm{CH}_{4}$ lines. There are no results available for the T-dependence of $\gamma \mathrm{o}$ for $\mathrm{CH}_{4}$-air or even $\mathrm{CH}_{4}-\mathrm{N}_{2}$ or $\mathrm{CH}_{4}-\mathrm{O}_{2}$ broadening. From the calculations and measurements for $\mathrm{CH}_{4}-\mathrm{H}_{2}$ broadening with T , we assume the usual $\mathrm{T}^{-1 / 2}$ dependence. In conclusion, for the present data compilation, we
use

$$
\begin{equation*}
\gamma^{0}=0.055\left(\frac{296}{T}\right)^{1 / 2}\left(\frac{p}{1 \text { atm }}\right) \tag{16}
\end{equation*}
$$

### 4.7 Oxygen

The infrared atmospheric bands of oxygen have been interpreted by Van Vleck as magnetic dipole transitions between intersystem electronic combinations, a singlet-triplet transition $\mathbf{a}^{\mathbf{1}} \mathbf{\Delta}_{\mathbf{g}}-\mathbf{X}^{\mathbf{3}} \mathbf{\Sigma}_{\mathbf{g}}^{\mathbf{g}}$. The A $\mathbf{v}=0(0,0)$ band at $7882.39 \mathrm{~cm}^{-1}$ $(1.27 \mu \mathrm{~m})$ has an Einstein A coefficient of $1.9 \times 10^{-4} \mathrm{sec}^{-1}$ Jones and Harrison (1958) . The $(0,0)$ band, and the weaker $(1,0)$ band at $9365.89 \mathrm{~cm}^{-1}$ have been observed in terrestial atmospheric absorption by Herzberg and Herzberg (1947). The $(0,1)$ band at $6325.99 \mathrm{~cm}^{-1}$ has been observed in the twilight airglow emission by Jones and Harrison (1958). In addition to these bands there is an electric quadrupole $\left(\mathrm{b}^{1} \mathrm{\Sigma}_{\mathrm{g}}^{+}-\mathrm{a}^{1} \Delta_{\mathrm{g}}\right)$ transition at $1.908 \mu \mathrm{~m}$ that has been detected in the emission spectrum of discharge through $\mathbf{0}_{2}$ and helium (Noxon, 1961). Finally, submillimeterwave rotational transitions (McKnight and Gordy, 1968) and spin reorientation spectra (Zimmerer and Mizushima. 1961) at 60 GHz have been observed in the ground electronic state. The (a-X) system and the microwave spectra are discussed below. The atmospheric "A" band at $7619 \AA$, representing the magnetic dipole transition $b^{1} \Sigma_{g}{ }^{+} \leftarrow \mathbf{X}^{3} \boldsymbol{\Sigma}_{\mathbf{g}}{ }^{-}$, is also included (Wark and Mercer. 1965; Burch and Gryunak, 1967).

With the molecular rotational momentum designated by $\underset{\mathcal{K}}{ }$ and the electronic spin vector by $\underset{\sim}{\mathbf{S}}$, the total angular momentum $\underset{\sim}{\mathcal{J}}$ is given by

## $\alpha=K+S$.

Thus, for the singlet-delta state $\mathbf{J}=\mathbf{K}$, and the energy levels, apart from the vibration, are given by

$$
\begin{equation*}
F=B_{v} K(K+1)-D_{v} K^{2}(K+1)^{2} \tag{17}
\end{equation*}
$$

where $B_{v}$ is the rotational constant and $D_{v}$ is the first order centrifugal distortion constant for the particular vibrational state. The constants for this state, obtained from measurements of the infrared bands, are listed in Table 27.

The expressions for the rotational energies of the rho-type triplet are obtained from a solution of the Hamiltonian (West and Mizushima, 1966):

$$
\begin{equation*}
H=B{\underset{\sim}{K}}^{2}+\frac{2}{3} \lambda\left(3 S_{z}^{2}-{\underset{\sim}{S}}^{2}\right)+\mu \mathbb{N} \cdot \underset{\sim}{S} \tag{18}
\end{equation*}
$$

where A is the spin-spin interaction coupling constant and $\boldsymbol{\mu}$ is the spin-rotation interaction coupling constant.

Table 27. Constants of the ${ }^{\mathbf{1}} \boldsymbol{\Delta}_{\mathbf{g}}$ State of $\mathbf{0}_{\mathbf{2}}$ (Herzberg and Herzberg, 1947)

| Constant | Value (in $\mathrm{cm}^{-1}$ ) |
| :--- | :---: |
| $\mathrm{B}_{\mathrm{o}}$ | 1.41783 |
| $\mathrm{~B}_{1}$ | 1.4007 |
| $\mathrm{D}_{\mathrm{o}}$ | $4.86 \times 10^{-6}$ |
| $\boldsymbol{\omega}_{\mathrm{e}^{-}}$ | 1509.3 |
| $\boldsymbol{\omega}_{\mathrm{e}_{e}}$ | 12.9 |
| $\boldsymbol{\nu}_{\mathrm{G}}$ |  |
| $\boldsymbol{\nu}_{\mathrm{e}}$ | 1483.50 |

Centrifugal stretching effects are approximately corrected for by assuming a $K(\mathrm{~K}+1)$ dependence for B . A and $\mu$, namely:

$$
\begin{align*}
& B=B_{v}-D_{v} K(K+1)+H_{v} K^{2}(K+1)^{2}, \\
& \lambda=\lambda_{0}-\lambda_{1} K(K+1), \text { and } \\
& \mu=u_{0}-\mu_{1} K(K+1) . \tag{19}
\end{align*}
$$

For each value of the quantum number at end-over-end rotation, $\mathbf{K}$, the triplet energies are given by $F_{1}(K), F_{2}(K)$, and $F_{3}(K)$ where $J=K+1, J=K$ and $J=K-1$, respectively. Both $\mathrm{F}_{1}(\mathrm{~K})$ and $\mathrm{F}_{3}(\mathrm{~K})$ average about $2 \mathrm{~cm}^{-1}$ lower than the $\mathrm{F}_{2}(\mathrm{~K})$ component. Values for the constants of the triplet-sigma state, obtained from both infrared and microwave measurements, are given in Table 28.

The band centers are given by

$$
\begin{align*}
& G\left(v^{\prime}, v^{\prime \prime}\right)=\nu_{e} e^{\prime}+\omega_{e}^{\prime}\left(v^{\prime}+1 / 2\right)-\omega_{e}^{\prime} x_{e}^{\prime}\left(v^{\prime}+1 / 2\right)^{2} t \ldots-\omega_{e}^{\prime \prime\left(v^{\prime \prime}+1 / 2\right)+} \\
& \omega_{e^{\prime \prime}}^{\prime \prime x_{e}^{\prime \prime}\left(v^{\prime \prime}+1 / 2\right)^{2}-\omega_{e^{\prime \prime}}^{\prime \prime} e^{\prime \prime}\left(v^{\prime \prime}+1 / 2\right)^{3}+\omega_{e}^{\prime \prime} z_{e}^{\prime \prime}\left(v^{\prime \prime}+1 / 2\right)^{4} t \ldots,} \tag{20}
\end{align*}
$$

where the prime and double primes refer to the singlet and triplet states respectively.

The selection rules for magnetic dipole radiation are

$$
\Delta \mathrm{J}=0,+1
$$

and

$$
+\cdots+,-\infty-\mathrm{g} \rightarrow \mathrm{~g}, \mathrm{u}-\mathrm{u} .
$$

Table 28. Constants for the ${ }^{\mathbf{3}} \boldsymbol{\Sigma}_{\mathbf{g}}^{-}$State of $\mathbf{0}_{\mathbf{2}}$

| Constant | Reference | Value ( $\mathrm{cm}^{-1}$ ) |

a. McKnight and Gordy (1968)
b. Babcock and Herzberg (1948)
c. West and Mizushima (1966)

The possible branches and the nomenclature used here for the ' $\mathbf{A}_{\mathbf{g}}-{ }^{\mathbf{3}} \boldsymbol{\Sigma}_{\mathbf{g}}^{-}$transition are shown in Table 27. Since the oxygen-16 nuclei obey Bose-Einstein statistics, only the positive rotational levels occur. In the ground state this causes an alternation of lines such that only odd values of the rotational quantum number $K$ are present. For the heteronuclcar isotopes of oxygen, however, all rotational levels occur; the $0^{17} 0^{17}$ molecule has alternate rotational levels with nuclear statistical weights of 5 and 7 (Gordy ct al, 1953). In $\mathbf{0}^{\mathbf{1 6}} \mathbf{0}^{16}\left(\right.$ and $\mathbf{0}^{18} \mathbf{0}^{18}$ ) there are four branches with $\Delta \mathrm{K}= \pm 1$, three with $\Delta \mathrm{K}=0$, and two with $\Delta \mathrm{K}= \pm 2$, the latter branches being designated by superscripts $S$ and 0 . On the magnetic tape the six quantum numbers of the transition, $v^{\prime}, J^{\prime}, K^{\prime}, v^{\prime \prime}, J^{\prime \prime}, K^{\prime \prime}$, are given in the field of columns 38 through 62. In addition. the nine branches are listed in columns 64 and 65 with the superscript, representing the AK of the transition, preceding the AJ designation. A diagram indicating the transitions involved in the ${ }^{\mathbf{1}} \boldsymbol{\Delta g}_{\mathbf{g}}{ }^{\mathbf{3}} \boldsymbol{\Sigma}_{\mathrm{g}}^{-}$band is given in Figure 1.

The above description generally applies to the microwave transitions of pure rotation and transitions between levels of the triplet state. In the latter the labelling is given as $\mathrm{K}^{+}$and K -, designating the transitions $\mathrm{F}_{2}(\mathrm{~K})-\mathrm{F}_{1}(\mathrm{~K})$ and $F_{2}(K)-F_{3}(K)$ respectively. Intensities have been calculated (see Townes and Schawlow, 1955). A good summary of the various bands of oxygen molecule can he found in the recent review article by Krupenie, 1972.

Figure 1. Transitions in the ${ }^{1} \Delta_{\mathbf{g}} \leftarrow^{3} \boldsymbol{\Sigma}_{\mathbf{g}}^{-}$Band of Oxygen

## 5. CONTINUOUS ABSORPTION BY ATMOSPHERIC GASES

Although not part of the data tape of primary concern in this report, a few words should be said about the relatively continuous regions of absorption of particular interest in the atmospheric "windows" near $2500 \mathrm{~cm}^{-1}(4 \mu \mathrm{~m})$, from approximately $1250 \mathrm{~cm}^{-1}$ to $700 \mathrm{~cm}^{-1}(8 \mu \mathrm{~m}-14 \mu \mathrm{~m})$, and near $450 \mathrm{~cm}^{-1}(22 \mu \mathrm{~m})$ In other spectral regions the contribution by nearby absorption lines is much greater than that by the continuum absorption, so that for practical purposes the continuum effect can be neglected, although it may be greater than in the windows.

This continuous absorption is caused by one or more of the following three processes: (1) extreme wings of strong collision-broadened absorption lines centered more than $10-20 \mathrm{~cm}^{-1}$ away; (2) pressure induced absorption resulting from transitions that are forbidden for unperturbed molecules; and (3) the possible existence of the water dimer $\left(\mathrm{H}_{2} 0: \mathrm{H}_{2} 0\right)$ in the case of the 8 to $14 \mu \mathrm{~m}$ region.

The absorption coefficient due to continuum absorption can be expressed as

$$
\begin{equation*}
k=C_{s} P_{s}+C_{b} P_{b} \tag{22}
\end{equation*}
$$

where $\mathrm{C}_{\mathrm{s}}$ is the self-broadened coefficient and $\mathrm{C}_{\mathrm{b}}$ is the foreign gas broadening coefficient, $\mathrm{P}_{\mathrm{s}}$ is the partial pressure of species, s , and $\mathrm{P}_{\mathrm{b}}$ is the foreign gas pressure.

Figure 3 gives the spectral dependence of $\mathbf{C}_{\mathbf{s}}$ for water vapor absorption in the 8 to $14 \mu \mathrm{~m}$ region for three temperatures (Burch, 1970). The $C_{b}$ value has been most reliably measured by McCoy et al, 1969, and is found for nitrogen to be $\mathbf{C}_{\mathbf{b}}=$ $0.005 \mathrm{C}_{\mathbf{s}}$ at room temperature.

Figure 2 gives the spectral dependence of $\mathbf{C}_{\mathbf{s}}$ for the water vapor absorption in the region near $4 \mu \mathrm{~m}$ for four different temperatures (Burch et al, 197la). Note that the $\mathbf{T}=\mathbf{2 9 6}{ }^{\circ} \mathrm{K}$ curve is an extrapolation based on the measurements at higher temperature. These same workers found the ratio $\mathbf{C}_{\mathbf{b}} / \mathbf{C}_{\mathbf{s}}$ for nitorgen broadening to be $0.12 \pm 0.03$.

Figure 4 gives the spectral dependence of the absorption coefficient due to the pressure-induced nitrogen absorption centered near $2330 \mathrm{~cm}^{-1}$ (Burch et al, 1971a) Measurements have also been made by Shapiro and Gush, 1966, and Farmer and Houghton, 1966. Since the foreign gas broadening in this case results from a gas (oxygen) having a constant mixing ratio in the atmosphere, Eq. (22) reduces to

$$
\begin{equation*}
\mathrm{K}=\text { Const. x } \mathrm{P} \tag{23}
\end{equation*}
$$

Since the nitrogen abundance in the atmosphere is also directly proportional to P , the absorption depends on $\mathrm{P}^{\mathbf{2}}$ and Figure 4 has as ordinate the absorption coefficien expressed in the units atm ${ }^{-2} \mathrm{Km}^{-1}$.

Since line wings as given by the Lorentz shape, Eq. (1), have been found to be in error in the extreme wings, an appropriate rule to follow for the truncation of

Figure 2. Normalized Continuum Absorption Coefficient for $\mathrm{H}_{2} \mathrm{O}$ at Three Temperatures

Figure 3. Normalized Continuum Absorption Coefficient Between 2400 and $2820 \mathrm{~cm}^{-1}$ for Pure $\mathrm{H}_{2} \mathrm{O}$ at Four Temperatures
line wings and the introduction of continuum absorption coefficients in accordance with Figures 2 through 4 is difficult to state. It is recommended that the user familiarize himself with this problem (see, for example, Burch et al, 1969) and in any case the use of the Lorentz shape beyond 20 or 30 wavenumbers of line centers is inappropriate (see also discussion on line shape on p. 3).

Figure 4. Spectral Plot of Absorption Coefficient for Atmospheric $\mathbf{N}_{2}$ at Four Temperatures

## Acknowledgments

We wish to acknowledge the contributions made by the many individuals to this data compilation through discussions, comments, and, in some cases, the use of preliminary laboratory spectra. Acknowledgment is particularly due to $\mathrm{S} . \mathrm{R}$. Drayson of the University of Michigan; C. B. Farmer and R. A. Toth, both of the Jet Propulsion Laboratories; A. G. Maki and W. J. Lafferty of the National Bureau of Standards; and R. Hanel and V. Kunde of the Goddard Space Flight Center, We further wish to acknowledge the help of D. Gryvnak of Philco Ford, Corp.; D. Murcray and A. Goldman of the University of Denver; T. Kyle of the National Center for Atmospheric Research; and B. Fridovich of the National Oceanic and Atmospheric Administration.

Particular mention should be made of the contribution made to this report by having access to the unpublished high-resolution solar spectra of D. N. B. Hall and J. Brault of the Kitt Peak National Observatory.

The help of J . Chetwynd of AFCRL in running and debugging computer programs, and the help of J. E. A. Selby, also of AFCRL, in checking some of the results is also recognized.

## Appendix B

The computer program (Program LBL) provided in this Appendix is intended for use as a check to ensure that a user of the AFCRL Data Tape will be using the data correctly. The spectral region chosen for a sample spectrum (Figure 5) contains spectral lines from four different atmospheric gases. The program was constructed for use with constant pressure and temperature paths only, so the user will be left to his own devices for real atmospheric applications. After computing transmittance at closely spaced monochromatic frequencies, a convolution is performed over a triangular slit function whose half-width can be chosen. Comment cards have been used freely, so no further discussion of this program will be given here.

Figure B1
Synthetic Spectrum Generated using the Data Compilation. Conditions are as follows: pressure $=$ $188 \mathrm{mb}, \mathrm{T}=219 \mathrm{~K}, \mathrm{WH} \mathrm{H}_{2} \mathrm{O}=2.00 \times 10^{20}, \mathrm{~W}_{\mathrm{CO}}=2.05 \times 10^{21}, \mathrm{WO}_{\mathrm{O}}=3.23 \times 10^{18}, \mathrm{~W}_{\mathrm{CO}}=4.67 \times$ 1017. Lines belor ${ }^{\text {ing }}$ to other molecular species contained on tape are not present in this spectral region. Spectrai resolution is $0.01 \mathrm{~cm}^{-1}$.

## a. abstract

The report describes a compilation of the molecular spectroscopic parameters for a number of infrared-active molecules occurring naturally in the terrestrial atmosphere. The following molecules are included in this compilation: water vapor; cat-bon dioxide; ozone; nitrous oxide; carbon monoxide; methane; and oxygen. The spectral region covered extends from less than $1 \mu \mathrm{~m}$ to the far infrared, and data are p:esented on more than 100,000 spectral lines. The parameters included in the compilation for each line are: frequency, intensity, half-width, energy of the lower state of the transition, vibrational and rotational identifications of the upper and lowes erergy states, an isotopic identification, and a molecular identification.

A discussion is provided separately for each molecular species, indicating the ssurces and accuracy of the data and a general discussion of how the data were ostained.
